Music theory

Contents

Chapter 1

Music theory

Music theory considers the practices and possibilities of music. It is generally derived from observation of how musicians and composers actually make music, but includes hypothetical speculation. Most commonly, the term describes the academic study and analysis of fundamental elements of music such as pitch, rhythm, harmony, and form, but also refers to descriptions, concepts, or beliefs related to music. Because of the ever-expanding conception of what constitutes music (see Definition of music), a more inclusive definition could be that music theory is the consideration of any sonic phenomena, including silence, as it relates to music.

Music theory is a subfield of musicology, which is itself a subfield within the overarching field of the arts and humanities. Etymologically, *music theory* is an act of contemplation of music, from the Greek θεωρία, a looking at, viewing, contemplation, speculation, theory, also a sight, a spectacle.[1] As such, it is often concerned with abstract musical aspects such as tuning and tonal systems, scales, consonance and dissonace, and rhythmic relationships, but there is also a body of theory concerning such practical aspects as the creation or the performance of music, orchestration, ornamentation, improvisation, and electronic sound production.[2] A person working in music theory is a music theorist. Methods of analysis include mathematics, graphic analysis, and, especially, analysis enabled by Western music notation. Comparative, descriptive, statistical, and other methods are also used.

The development, preservation, and transmission of music theory may be found in oral and practical music-making traditions, musical instruments, and other artifacts. For example, ancient instruments from Mesopotamia, China,[3] and prehistoric sites around the world reveal details about the music they produced and, potentially, something of the musical theory that might have been used by their makers (see History of music and Musical instrument). In ancient and living cultures around the world, the deep and long roots of music theory are clearly visible in instruments, oral traditions, and current music making. Many cultures, at least as far back as ancient Mesopotamia, Pharoanic Egypt, and ancient China have also considered music theory in more formal ways such as written treatises and music notation.

1.1 History of music theory

Egyptian musicians playing lutes in an ensemble.

The beginnings of music theory can be observed in extremely ancient instruments, artifacts, and later, depictions of performance in artworks.

As early as the Paleolithic, it appears people considered elements of music in some way. For instance, a bone flute with carefully placed finger holes found in Hohle Fels in Germany and dated c.35,000 BCE,[4] may be a prehistoric example of the manufacture of an instrument to produce a preconceived set of pitches. For further discussion of Upper Paleolithic flutes, see d'Errico, et al. 2003, 39–48.

Similar bone flutes (gǔdí, ????) from Neolithic Jiahu, China dated c. 7,000 BCE[5] reveal their makers progressively added more holes to expand their scales, structured pitch intervals closer to each other to adjust tuning, and could play increasingly expressive and varied music.[6] "Tonal analysis of the flutes revealed that the seven holes [in some of the flutes] correspond to a tone scale remarkably similar to Western eight-pitch scales."[7][8] These instruments[9] indicate their makers became familiar with acoustics and developed theories of music comparable to those of later times. Audio recordings of two of these flutes by Brookhaven National Laboratory are available here.

In North America, similar flutes from the Anasazi In-

dian culture were found in Arizona and dated c. 600–750 CE, but again, suggest an older tradition. These instruments typically have six finger holes ranging one and a half octaves.[10] As with all these ancient flutes, it is likely an error to imagine the Anasazi flutes were limited to only as many tones as they have holes. Changes in embouchure, overblowing, and cross-fingering are common techniques on modern flutes like these that produce a much larger range of notes within an octave and in octaves above the fundamental octave.[11]

The earliest known examples of written music theory are inscribed on clay tablets found in Iraq and Syria, some of which contain lists of intervals and other details[12][13] from which "...musicologists have been able to produce credible reconstructions of the Mesopotamian tonal and tuning systems."[14] Tablets from Ugarit contain what are known as the Hurrian songs or Hurrian Hymns dated c. 1,400 BCE. An interpretation of the only substantially complete Hurrian Hymn, h.6, may be heard here. The system of phonetic notation in Sumer and Babylonia is based on a music terminology that gives individual names to nine musical strings or "notes", and to fourteen basic terms describing intervals of the fourth and fifth that were used in tuning string instruments (according to seven heptatonic diatonic scales), and terms for thirds and sixths that appear to have been used to fine tune (or temper in some way) the seven notes generated for each scale.[15][16][17][18][19]

Over time, many cultures began to record their theories of music in writing by describing practices and theory that was previously developed and passed along through oral tradition. In cultures where no written examples exist, oral traditions indicate a long history of theoretical consideration, often with unique concepts of use, performance, tuning and intervals, and other fundamental elements of music. The Vedas, the sacred texts of India (c. 1,000–500 BCE) contain theoretical discussion of music in the Sama Veda and Yajur-Veda, however, these texts are widely considered to be based on far older oral traditions. The *Natya Shastra*,[20] written between 200 BCE to 200 CE and attributed to Bharata Muni, discusses classes of melodic structure, intervals, consonance and dissonance, performance, and other theoretical aspects such a "shruti," defined as the least perceivable difference between two pitches.[21]

The music of pre-Columbian Mesoamerica is known through the many instruments discovered. Thirty-two condor-bone flutes and thirty-seven cornet-like instruments made of deer and llama bones have been recovered from a site at Caral, Peru dating to c. 2,100 BCE.[22][23][24] Flute No. 15 produces five distinct fundamental tones. A Mayan marimba-like instrument (c. 350 CE), made from five turtle shells of decreasing sizes suspended on a wooden frame, has been discovered in Belize.[25] Later artwork depicts ensemble and solo performance. Taken together, this evidence does not in itself demonstrate anything about music theory in Mesoamerica from at least 2,000 BCE, though "...it is widely accepted that finds and depictions of ancient musical instruments are not only markers of musical traditions in space and time. … The information obtained from the archaeological record can be deepened considerably when ancient scripts, historical treaties, and other written sources concerning music are related. Such documents offer notes on performance practices and their sociocultural contexts. For some cultures, hints concerning ancient music theory and musical aesthetics may also be found."[26]

Music theory in ancient Africa can also be seen in instruments .[27] The Mbira, a wood or bamboo-tined instrument similar to a Kalimba, appeared on the west coast of Africa about 3,000 years ago, and metal-tined lamellophones appeared in the Zambezi River valley around 1,300 years ago.[28] In the 20th century, these instruments produce a number of tones, ranging to 32 separate pitches, and demonstrate a great variety of tunings—tunings "so dissimilar as to offer no apparent common foundation", something that might have been expected at least by 1932.[29] The djembe, a common type of drum, likely originated from earlier, extremely ancient drums.[30] Djembe ensembles create complex polyrhythmic patterns,[31] but produce a variety of pitches depending on size and playing technique, usually producing at least three separate tones.[32] African music theory is also preserved in oral and cultural traditions that are one example of the great variety of concepts of fundamental aspects of music around the world.[33]

In China, a variety of wind, string, percussion instruments, and written descriptions and drawings of them from the Shang Dynasty (c.16th to 11th century BCE), show sophisticated form and design.[34] During the Zhou Dynasty (c. 1046–256 BC), a formal system of court and ceremonial music later termed "yayue" was established. As early as the 7th century BCE, a system of pitch generation was described based on a ratio of 2:3 and a pentatonic scale was derived from the cycle of fifths,[35] the beginnings of which may be seen in the 7,000 year-old Jiahu bone flutes. In the tomb of the Marquis Yi of Zeng (5th century BCE), among many other instruments, a set of bronze chime bells were found that sound five complete seven note octaves in the key of C Major and include twelve semitones.[36] The Analects of Confucius, believed to have been written c. 475 to 221 BC, discuss the aesthetics of what Confucius considered to be the most benevolent form and use of music, in contrast to popular music of his time—an example of early music criticism and consideration of aesthetics.[37][38]

Around the time of Confucius, the ancient Greeks, notably Pythagoras (c. 530 BCE), Aristotle (c. 350 BCE),[39] Aristoxenus (c. 335 BCE),[40] and later Ptolemy (c. 120 CE),[41] speculated and experimented with ideas that became the basis of music theory in Middle Eastern and Western cultures during the Middle Ages as can be seen, for example, in the writing of Boethius in 5th century Rome[42] and Yunus al-Katibin 7th cen-

Set of bells from China. 5th Century BCE.

tury Medina.[43] Middle Eastern and Western theory diverged in different directions from ancient Greek theory and created what are now two distinctly different bodies of theory and styles of music.

As Western musical influence spread throughout the world in the 1800s, Western theory became adopted as an international standard, but many other theoretical traditions in both textual and oral traditions continue to be used to create the distinctive music of the world's cultures. For example, the long and rich musical traditions unique to ancient and current cultures of Africa are primarily oral, but inherently contain consideration of specific forms, genres, performance practices, as well as tuning, and other aspects of music theory.[44][45]

Among the major contributors to the field are the ancient Greeks Archytas, Aristotle, Aristoxenus, Eratosthenes, Plato, Pythagoras, and later Ptolemy; in the Middle Ages of Europe, Boethius, Franco of Cologne, Guido of Arezzo, Hucbald of Saint-Amand, Jacob of Liège, Jean de Muris; later in Europe, Zarlino, Rameau, Werckmeister, Fux; more recently, Riemann, Schenker, Boulanger, and Schoenberg (see List of music theorists); in India, Bharata Muni, Vishnu Narayan Bhatkhande, Purandara Dasa, Sharngadeva; in the Middle East, Ibn Misjah, Ibrahim al-Mawsili and his son Ishaq, Yunus al-Katib, Ibn Sina (known in Europe as Avicenna); in China, Confucius, Yong Menzhoue, and Cao Rou.

1.2 Fundamentals of music

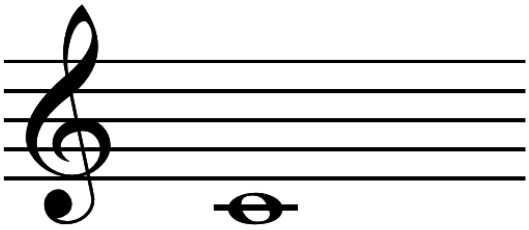
Main article: Aspect of music

Music is composed of phenomena of sound and "music theory" considers how those phenomena are and can be used in music. Music theory includes considerations of melody, rhythm, counterpoint, harmony and form; tonal systems, scales, tuning, intervals, consonance, dissonance, durational proportions and the acoustics of pitch systems; composition, performance, orchestration, ornamentation, improvisation and electronic sound production; etc.[46]

1.2.1 Pitch

Main article: Pitch (music)

Pitch is the lowness or highness of a tone, for example the difference between middle C and a higher C. The frequency of the sound waves producing a pitch can be measured precisely, but the perception of pitch is more complex because we rarely hear a single frequency or pure pitch. In music, tones, even those sounded by solo instruments or voices, are usually a complex combination of frequencies, and therefore a mix of pitches. Accordingly, theorists often describe pitch as a subjective sensation.[47] Most people appear to possess relative pitch, which means they perceive each note relative to some reference pitch, or as some interval from the previous pitch. Significantly fewer people demonstrate absolute pitch (or perfect pitch), the ability to identify pitches without comparison to another pitch. Human perception of pitch can be comprehensively fooled to create auditory illusions. Despite these perceptual oddities, perceived pitch is nearly always closely connected with the fundamental frequency of a note, with a lesser connection to sound pressure level, harmonic content (complexity) of the sound, and to the immediately preceding history of notes heard.[48] In general, the higher the frequency of vibration, the higher the perceived pitch. The lower the frequency, the lower the pitch.[49] However, even for tones of equal intensity, perceived pitch and measured frequency do not stand in a simple linear relationship.[50]



Middle C (261.626 Hz) Play .

Intensity (loudness) can change perception of pitch. Below about 1000 Hz, perceived pitch gets lower as intensity increases. Between 1000 and 2000 Hz, pitch remains fairly constant. Above 2000 Hz, pitch rises with intensity.[51] This is due to the ear's natural sensitivity to higher pitched sound, as well as the ear's particular sensitivity to sound around the 2000–5000 Hz interval,[52] the frequency range most of the human voice occupies.[53]

The difference in frequency between two pitches is called an interval. The most basic interval is the unison, which is simply two notes of the same pitch, followed by the slightly more complex octave: pitches that are either double or half the frequency of the other. The unique characteristics of octaves gave rise to the concept of what is called pitch class, an important aspect of music theory. Pitches of the same letter name that occur in different

octaves may be grouped into a single “class” by ignoring the difference in octave. For example, a high C and a low C are members of the same pitch class—that class which contains all C’s. The concept of pitch class greatly aids aspects of analysis and composition.[54]

Although pitch can be identified by specific frequency, the letter names assigned to pitches are somewhat arbitrary. For example, today most orchestras assign Concert A (the A above middle C on the piano) to the specific frequency of 440 Hz, rather than, for instance, 435HZ as it was in France in 1859. In England, that A varied between 439 and 452. These differences can have noticeable affect on the timbre of instruments and other phenomena. Many cultures do not attempt to standardize pitch, often considering that it should be allowed to vary depending on genre, style, mood, etc. In historically informed performance of older music, tuning is often set to match the tuning used in the period in which it was written. A frequency of 440 Hz was recommended as the standard pitch for Concert A in 1939, and in 1955 the International Organization for Standardization affirmed the choice.[55] A440 is now widely, though not exclusively, the standard for music around the world.

Pitch is also an important consideration in tuning systems, or temperament, used to determine the intervallic distance between tones, as within a scale. Tuning systems vary widely within and between world cultures. In Western culture, there have long been several competing tuning systems, all with different qualities. Internationally, the system known as equal temperament is most commonly used today because it is considered the most satisfactory compromise that allows instruments of fixed tuning (e.g. the piano) to sound acceptably in tune in all keys.

1.2.2 Scales and modes

Main articles: Musical scale and Musical mode

Notes can be arranged in a variety of scales and modes.

Pattern of whole and half steps in the Ionian mode or major scale on C Play .

Western music theory generally divides the octave into a series of twelve tones, called a chromatic scale, within which the interval between adjacent tones is called a half step or semitone. In equal temperament each semitone is equidistant from the next, but other tuning systems are also used. Selecting tones from this set of 12 and arranging them in patterns of semitones and whole tones creates other scales. The most commonly encountered scales are the seven-toned major, the harmonic minor, the melodic minor, and the natural minor. Other examples of scales are the octatonic scale and the pentatonic or five-tone scale, which is common in folk music and blues. Non-Western cultures often use scales that do not correspond with an equally divided twelve-tone division of the octave. For example, classical Ottoman, Persian, Indian and Arabic musical systems often make use of multiples of quarter tones (half the size of a semitone, as the name indicates), for instance in 'neutral' seconds (three quarter tones) or 'neutral' thirds (seven quarter tones) – they do not normally use the quarter tone itself as a direct interval, however.[56]

In traditional Western notation, the scale used for a composition is usually indicated by a key signature at the beginning to designate the pitches that make up that scale. As the music progresses, the pitches used may change and introduce a different scale. Music can be transposed from one scale to another for various purposes, often to accommodate the range of a vocalist. Transposition raises or lowers the overall pitch range, but preserves the intervallic relationships of the original scale. For example, transposition from the key of C major to D major raises all pitches of the scale of C major equally by a whole tone. Since the interval relationships remain unchanged, transposition may be unnoticed by a listener, however other qualities may change noticeably because transposition changes the relationship of the overall pitch range compared to the range of the instruments or voices that perform the music. This often affects the music’s overall sound, as well as having technical implications for the performers.[57]

The interrelationship of the keys most commonly used in Western tonal music is conveniently shown by the circle of fifths. Unique key signatures are also sometimes devised for a particular composition. During the Baroque period, emotional associations with specific keys, known as the doctrine of the affections, were an important topic in music theory, but the unique tonal colorings of keys that gave rise to that doctrine were largely erased with the adoption of equal temperament. However, many musicians continue to feel that certain keys are more appropriate to certain emotions than others. Indian classical music theory continues to strongly associate keys with emotional states, times of day, and other extra-musical concepts and notably, does not employ equal temperament.

1.2.3 Consonance and dissonance

Main article: Consonance and dissonance

Consonance and dissonance are subjective qualities of the sonority of intervals that vary widely in different cultures and over the ages.

Consonance (or concord) is the quality of an interval or chord which seems stable and complete in itself. Dissonance (or discord) is the opposite in that it feels in-

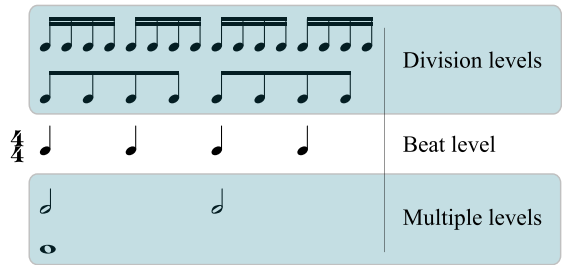
complete and "wants to" resolve to a consonant interval. Dissonant intervals seem to clash. Consonant intervals seem to sound comfortable together. Commonly, perfect fourths, fifths, and octaves and all major and minor thirds and sixths are considered to be consonant. All others are dissonant to greater or lesser degree. However, context and many other aspects can affect apparent dissonance and consonance. For example, in a Debussy prelude, a major second may sound stable and consonant, while the same interval may sound dissonant in a Bach fugue. In the Common Practice era, the perfect fourth is considered dissonant when not supported by a lower third or fifth. Since the early 20th century, Arnold Schoenberg's concept of "emancipated" dissonance, in which traditionally dissonant intervals can be treated as "higher," more remote consonances, has become more widely accepted.[58]

Dissonance is an essential element of music and used in most every culture and genre, not only for effect, but as a fundamental structural element to create motion and tension. J.S. Bach's music depends in great part on the effect of dissonance. The art of melody writing depends heavily upon the selection of consonant and dissonant tones.

1.2.4 Rhythm

Main article: Rhythm

Rhythm is produced by the sequential arrangement of



Metric levels: beat level shown in middle with division levels above and multiple levels below.

sounds and silences in time. Meter measures music in regular pulse groupings, called measures or bars. The time signature or meter signature specifies how many beats are in a measure, and which value of written note is counted or felt as a single beat. Through increased stress, or variations in duration or articulation, particular tones may be accented. There are conventions in most musical traditions for regular and hierarchical accentuation of beats to reinforce a given meter. Syncopated rhythms contradict those conventions by accenting unexpected parts of the beat. Playing simultaneous rhythms in more than one time signature is called polymeter. See also polyrhythm.

In recent years, rhythm and meter have become an important area of research among music scholars. Recent work in these areas includes books by Bengt-Olov Palmqvist, Fred Lerdahl and Ray Jackendoff, and Jonathan Kramer.

1.2.5 Chord

Main article: Chord (music)

A chord is group of tones heard or conceived as sounding simultaneously. In some instances, tones of a chord not sounding simultaneously but successively, for example in an arpeggio, in compound melody, or in the style brisé, may still be considered to form a chord. There is ongoing debate about the minimum number of tones required to constitute a chord: two, or three (see chord). The exploitation of chords and their patterns of succession or progression is a prominent feature of Western music, but is also found in other cultures. The study of chords is a primary concern of music theory for many reasons, but especially their significance in, and effect upon harmony, counterpoint, form, and tension and release.

In common-practice harmony, chords are often formed of three tones in stacked thirds; such three-tone chords are called triads. They consist of a primary tone called the root, a second tone a third above the root, and another tone a third above that (that is, a fifth above the root). Triads take the name of their root tone (e.g. C, F, or E) and are further described by the quality of the intervals between their tones (e.g. A major, C minor, E diminished). Chords may be inverted by changing the vertical arrangement of tones, extended by adding tones which in the common definition of consonance and dissonance necessarily are dissonant, or altered by modifying one or several of their tones usually by a chromatic semitone. Seventh chords consist of a triad plus an additional tone a third above the fifth, i.e. a major seventh (in the case of major triads), minor seventh (in the case of diminished, minor, or major triads), or diminished seventh (only in the case of diminished triads) above the root. Clusters are built by vertical arrangements of adjacent tones.

1.2.6 Melody

Main article: Melody

A melody is a series of tones sounding in succession that

"Pop Goes the Weasel" melody[59] *Play*

typically move toward a climax of tension then resolve to a state of rest. Because melody is such a prominent aspect in so much music, its construction and other qualities are a primary interest of music theory.

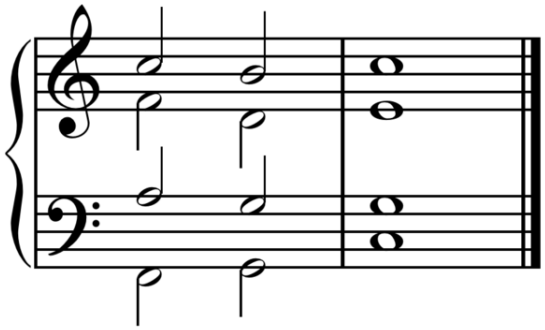
The basic elements of melody are pitch, duration, rhythm, and tempo. The tones of a melody are usually drawn

from pitch systems such as scales or modes. Melody may consist, to increasing degree, of the figure, motive, semiphrase, antecedent and consequent phrase, and period or sentence. The period may be considered the complete melody, however some examples combine two periods, or use other combinations of constituents to create larger form melodies.[60]

1.2.7 Harmony

Main article: Harmony

Harmony is the study of vertical sonorities in music. Ver-



IV-V-I progression in C Play

tical sonority is produced by the relationships of pitches that occur together; usually this means at the same time, although harmony can also be implied by a melody that outlines a harmonic structure. How tones sound together and in succession to create what we recognize as music is a principal concern in music theory.

In Western music of the Common Practice Era, harmonies are generally tertian. This means that the intervals of which the chords are composed are a third—not that the chord is necessarily a triad (composed of three notes). Quartal and quintal harmony are built on the interval of a fourth and fifth, respectively. In tertian harmony, a root-position triad (with the root note in the lowest voice) consists of the root note, a note a third above, and a note a third above that (a fifth above the root). Seventh chords add a fourth note, a third above the top note of a triad (a seventh above the root). In 20th century classical music and jazz, many alternative types of harmony are explored: modal, quartal, etc. One way to analyze harmony is through a Roman numeral system whereby Roman numerals are used to identify chords based on their scalar roots (I through VII). in popular music and jazz a system of chord symbols is commonly used (Cmaj7, E9, etc.). post-tonal music employs a variety of approaches, most frequently set theory.

1.2.8 Texture

Main article: Musical texture

Musical texture is the overall sound of a passage or com-

Introduction to Sousa's "Washington Post March," m. 1-7 Play features octave doubling (Benward & Saker 2003, 133) and a homorhythmic texture.

plete composition, commonly described according to the number of and relationship between parts or lines of music: monophony, heterophony, polyphony, homophony, or monody. The perceived texture of a piece can also be affected by the timbre of the instruments, the number of instruments used, and the intervallic distance between each musical line, among other things. Its theoretical interest includes its effects on perception, form, and style.

1.2.9 Timbre

Main article: Timbre

Timbre, sometimes called “color”, or “tone color,” is the principal phenomenon that allows us to distinguish one instrument from another when both play at the same pitch and volume, a quality of a voice or instrument often described in terms like bright, dull, shrill, etc. It is of considerable interest in music theory, especially because it is one component of music that has as yet, no standardized nomenclature. It has been called "...the psychoacoustician’s multidimensional waste-basket category for everything that cannot be labeled pitch or loudness,”[61] but can be accurately described and analyzed by Fourier analysis and other methods[62] because it results from the combination of all sound frequencies, attack and release envelopes, and other qualities that comprise a tone.

Timbre is principally determined by two things: (1) the relative balance of overtones produced by a given instrument due its construction (e.g. shape, material), and (2) the envelope of the sound (including changes in the overtone structure over time). Timbre varies widely between different instruments, voices, and to lesser degree, between instruments of the same type due to variations in their construction, and significantly, the performer’s technique. The timbre of most instruments can be changed by employing different techniques while playing. For example, the timbre of a trumpet changes when a mute is inserted into the bell, the player changes their embouchure, or volume. A voice can change its timbre by the way the performer manipulates their vocal apparatus, (e.g. the shape of the vocal cavity or mouth). Musical notation frequently specifies alteration in timbre by changes in sounding technique, volume, accent, and other means. These are indicated variously by symbolic and verbal instruction. For example, the word *dolce* (sweetly) indicates a non-specific, but commonly understood soft and “sweet”

timbre. *Sul tasto* instructs a string player to bow near or over the fingerboard to produce a less brilliant sound. *Cuivre* instructs a brass player to produce a forced and stridently brassy sound. Accent symbols like *marcato* (^) and dynamic indications (*pp*) can also indicate changes in timbre.

1.2.10 Expression

Main article: Musical expression

Expression is created by nuances of any phenomena of sound including timbre, variation of pitch, tempo, volume, etc. Due to its great effect on perception and emotional response, it is of particular interest in music theory. Although frequently indicated in music notation verbally or by symbols, those indications are imprecise in comparison to elements like pitch, and so highly dependent on the interpretation and performance of the player. For example, although pianissimo *pp* and the word *dolce* indicate a low volume and sweet or tender feeling, precisely how quietly and with what technique they may be played is subject to the player's interpretation. Common music notation is incapable of directing every aspect of a player's performance.

Dynamics

Main article: Dynamics (music)

In music, "dynamics" normally refers to variations of

intensity or volume, as may be measured by physicists and audio engineers in decibels or phons. In music notation, however, dynamics are not treated as absolute values, but a relative ones. Because they are usually measured subjectively, there are factors besides amplitude that affect the performance or perception of intensity, such as timbre, vibrato, and articulation. The conventional indications of dynamics are abbreviations for Italian words like *forte* (***f***) for loud and *piano* (***p***) for soft. These two basic notations are modified by indications including *mezzo piano* (***mp***) for moderately soft (literally "half soft") and *mezzo forte* (***mf***) for moderately loud, *sforzando* or *sforzato* (***sfz***) for a surging or "pushed" attack, or *fortepiano* (***fp***) for a loud attack with a sudden decrease to a soft level. The full span of these markings usually range from a nearly inaudible *pianississississimo* (***pppp***) to a loud-as-possible *fortissississississimo* (***ffff***). Greater extremes of ***pppppp*** and ***fffff*** and nuances such as ***p+*** or *più piano* are sometimes found. Other systems of indicating volume are also used in both notation and analysis: dB (decibels), numerical scales, colored or different sized notes, words in languages other than Italian, and symbols such as those for progressively increasing volume (*crescendo*) or decreasing volume (*decrescendo*), often called "hairpins" when indicated with diverging or converging lines as shown in the graphic above.

Articulation

Main article: Articulation (music)

Articulation is the manner in which the performer sounds

Examples of articulations. From left to right: staccato, staccatissimo, martellato, marcato, tenuto.

notes. For example, *staccato* is the shortening of duration compared to the written note value, *legato* performs the notes in a smoothly joined sequence with no separation. Articulation is often described rather than quantified, therefore there is room to interpret how to execute precisely each articulation. For example, *staccato* is often referred to as "separated" or "detached" rather than having a defined or numbered amount by which to reduce the notated duration. But, for example, violin players use a variety of techniques to perform different qualities of *staccato.* The manner in which a performer decides to execute a given articulation is usually based on the context of the piece or phrase, but many articulation symbols and verbal instructions depend on the instrument and musical period (e.g. viol, wind; classical, baroque; etc.). There is a set of articulations that most all instruments and voices perform in common. They are, in order of long to short: *legato* (smooth, connected); *tenuto* (pressed or played to full notated duration); *marcato* (accented and detached); *staccato* ("separated", "detached"); *martelé* (heavily accented or "hammered"). Many of these can be combined to create certain "in-between" articulations. For example, *portato* is the combination of *tenuto* and *staccato*. Some instruments have unique methods by which to produce sounds, such as *spicatto* for bowed strings, where the bow bounces off the string.

1.2.11 Form or structure

Main article: Musical form

Form is an important area of music theory that considers the structure, both local and global, of a composition. Examples of common forms of Western music include sonata-allegro, canon, strophic, theme and variation, and rondo. Popular Music often makes use of ballad form

many times in conjunction with twelve-bar blues. In Indian music, raga is an important form. Although classification of a musical form is useful in study and appreciation, composers vary and combine forms to such a degree that the model or "the rule" is usually outnumbered by the exceptions. Fugue is often considered as a distinct form, and even though many compositions are titled as such, most fugues bear little structural resemblance to others. The aspect they have in common is often only the process by which melodies are combined and altered. Accordingly, fugue is perhaps more accurately considered to be a process, rather than a form.

1.2.12 Performance and style

Main article: Music genre

Since music is generally written to be performed, consideration of performance and style is inherent in music theory. Notation is the attempt by the composer to clearly and accurately communicate how the music is intended to be performed. Theory also considers performance practices and standards from previous eras, many of which are based on style or genre, especially the problem of changing interpretation of symbols and verbal instructions over time. For examples, symbols for mordents and turns and tempo indications such as Andante were performed differently in the Baroque period than today. The violin bow was shaped in a high arc, like a hunting bow, in the Renaissance and early Baroque, with significant effect on performance technique.

Performance is an integral aspect of style, but style also includes consideration of forces (number of players in sections), interpretation of notation markings like staccato, genre, and many other aspects.

1.3 Music subjects

1.3.1 Notation

Main articles: Musical notation and Sheet music

Musical notation is the written or symbolized representation of music. This is most often achieved by the use of commonly understood graphic symbols and written verbal instructions and their abbreviations. Computer file formats have become important as well.[63] Spoken language and hand signs are also used to symbolically represent music, primarily in teaching.

Tibetan musical score from the 19th century.

In standard Western music notation, tones are represented graphically by symbols (notes) placed on a staff or staves, the vertical axis corresponding to pitch and the horizontal axis corresponding to time. Note head shapes, stems, flags, ties and dots are used to indicate duration. Additional symbols indicate keys, dynamics, accents, rests, etc. Verbal instructions are often used to indicate tempo, technique, and other aspects.

There are many systems of music notation from different cultures and different ages. Traditional Western notation evolved during the Middle Ages and continues to be an area of experimentation and innovation.[64]

1.3.2 Mathematics

Main article: Music and mathematics

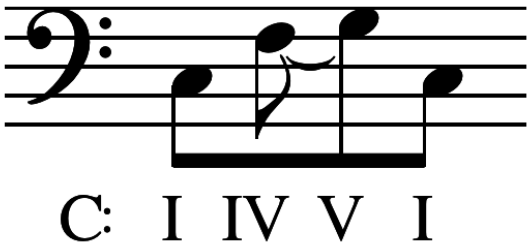
Mathematics are an integral part of music theory and have been for thousands of years. Early analyses of harmony and intervals (see Pythagoras) were often done with mathematical principles (e.g. dividing a string in half to find the octave, or the pitch that is twice the frequency of the fundamental tone). Maths are also used to consider form and structure, stylistic tendencies, instrument manufacture, tuning systems, and many other aspects. Some

methods of composition, especially computer-assisted composition, rely on mathematics. (see Computer music) Many electronic instruments use a mathematical system known as MIDI (musical instrument digital interface) to specify and control pitch, duration, volume, tempo and other aspects of sound.

1.3.3 Analysis

Main articles: Musical analysis, Schenkerian analysis and Transformational theory

Analysis is the effort to describe and explain music.



Bass prolongation: I–IV–V–I Play as elaboration of I–V–I Play

.

Analysis at once is a catch-all term describing the process of describing any portion of the music, as well as a specific field of formal analysis or the field of stylistic analysis. Formal analysis attempts to answer questions of hierarchy and form, and stylistic analysis attempts to describe the style of the piece. These two distinct sub-fields often coincide.

Analysis of harmonic structures is typically presented through a Roman numeral analysis. However, over the years, as music and the theory of music have both grown, a multitude of methods of analyzing music have presented themselves. Two very popular methods, Schenkerian analysis and Neo-Riemannian analysis, have dominated much of the field. Schenkerian analysis attempts to "reduce" music through layers of foreground, middleground, and, eventually and importantly, the background. Neo-Riemannian (or Transformational) analysis began as an extension of Hugo Riemann's theories of music, and then expanding Riemann's concepts of pitch and transformation into a mathematically rich language of analysis. While both theories originated as methods of analysis for tonal music, both have been extended to use in non-tonal music as well.

1.3.4 Ear training

Main article: Ear training

Aural skills – the ability to identify musical patterns by ear, as opposed to by the reading of notation – form a key part of a musician's craft and are usually taught alongside music theory. Most aural skills courses train the perception of relative pitch (the ability to determine pitch in an established context) and rhythm. Sight-singing – the ability to sing unfamiliar music without assistance – is generally an important component of aural skills courses. Absolute pitch or perfect pitch describes the ability to recognize a particular audio frequency as a given musical note without any prior reference.

Chapter 2

Musical notation

"Music markup" redirects here. For the XML application, see Music Markup Language.

Music notation or **musical notation** is any system used to visually represent aurally perceived music through the use of written symbols, including ancient or modern musical symbols. Types and methods of notation have varies between cultures and throughout history, and much information about ancient music notation is fragmentary.

Hand-written musical notation by J. S. Bach: beginning of the Prelude from the Suite for Lute in G minor BWV 995 (transcription of Cello Suite No. 5, BWV 1011) BR Bruxelles II. 4805.

Although many ancient cultures used symbols to represent melodies, none of them is nearly as comprehensive as written language, limiting our modern understanding. Comprehensive music notation began to be developed in Europe in the Middle Ages, and has been adapted to many kinds of music worldwide.

2.1 History

2.1.1 Ancient Near East

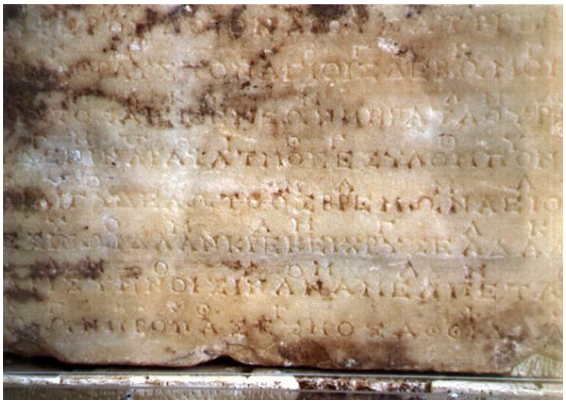
Further information: Music of Mesopotamia and Hurrian songs

The earliest form of musical notation can be found in a cuneiform tablet that was created at Nippur, in Sumer (today's Iraq), in about 2000 BC. The tablet represents fragmentary instructions for performing music, that the music was composed in harmonies of thirds, and that it was written using a diatonic scale.[1] A tablet from about 1250 BC shows a more developed form of notation.[2] Although the interpretation of the notation system is still controversial, it is clear that the notation indicates the names of strings on a lyre, the tuning of which is described in other tablets.[3] Although they are fragmentary, these tablets represent the earliest notated melodies found anywhere in the world.[4]

2.1.2 Ancient Greece

Further information: Musical system of ancient Greece

Ancient Greek musical notation was in use from at least the 6th century BC until approximately the 4th century AD; several complete compositions and fragments of compositions using this notation survive. The notation consists of symbols placed above text syllables. An example of a complete composition is the Seikilos epitaph, which has been variously dated between the 2nd century BC to the 1st century AD. Three hymns by Mesomedes of Crete exist in manuscript. The Delphic Hymns, dated to the 2nd century BC, also use this notation, but they are not completely preserved. Ancient Greek notation appears to have fallen out of use around the time of the Decline of the Roman Empire.



Photograph of the original stone at Delphi containing the second of the two hymns to Apollo. The music notation is the line of occasional symbols above *the main, uninterrupted line of Greek lettering.*

2.1.3 Byzantine Empire

Further information: Byzantine music

Byzantine music is vocal religious music, based on the

Byzantine music notation style in a Romanian "Book of Hymns at the Lord's Resurrection", 1823

monodic modal singing of Ancient Greece and the pre-Islamic Near East. The notation developed for it is similar in principle to subsequent Western notation, in that it is ordered left to right, and separated into measures. The main difference is that notation symbols are *differential* rather than absolute, i.e. they indicate pitch *change* (rise or fall), and the musician has to deduce correctly, from the score and the note they are singing presently, which note comes next. The pitch symbols themselves resemble brush strokes and are colloquially called *gántzoi* ("hooks") in Modern Greek. Notes themselves are represented in written form only between measures, as an optional reminder, along with modal and tempo directions if needed. Additional signs are used to indicate embellishments and microtones (pitch changes smaller than a semitone), both essential in Byzantine chant (*see* Romanian anastasimatarion *picture, left*).

The seven standard note names in Byzantine "solfege" are: *pá, vú, g^há, d^hē, ké, zō, nē*, corresponding to Western *re, mi, fa, sol, la, si, do*. Byzantine music uses the eight natural, non-tempered scales called *Ēkhoi*, "sounds", exclusively, and therefore the absolute pitch of each note may slightly vary each time, depending on the particular *Ēkhos* used. Byzantine notation is still used in many Orthodox Churches. Some cantors can also use standard Western notation while adding non-notatable embellishment material from memory and "sliding" into the natural scales from experience.

2.1.4 South West Asia

In 1252, Safi al-Din al-Urmawi developed a form of musical notation, where rhythms were represented by geometric representation. Many subsequent scholars of rhythm have sought to develop graphical geometrical notations. For example, a similar geometric system was published in 1987 by Kjell Gustafson, whose method represents a rhythm as a two-dimensional graph.[5]

2.1.5 Early Europe

Scholar and music theorist Isidore of Seville, writing in the early 7th century, considered that "unless sounds are held by the memory of man, they perish, because they cannot be written down."[6] By the middle of the 9th century, however, a form of neumatic notation began to develop in monasteries in Europe as a mnemonic device for Gregorian chant, using symbols known as neumes; the earliest surviving musical notation of this type is in the *Musica disciplina* of Aurelian of Réôme, from about 850. There are scattered survivals from the Iberian Peninsula before this time, of a type of notation known as Visigothic neumes, but its few surviving fragments have not yet been deciphered.[7] The problem with this notation was that it only showed melodic contours and consequently the music could not be read by someone who did not know the music already.

To address the issue of exact pitch, a staff was introduced consisting originally of a single horizontal line, but this was progressively extended until a system of four parallel, horizontal lines was standardized. This is traditionally attributed to Guido of Arezzo, who set out his thoughts on the changes in his first musical treatise, *Micrologus*.

Early music notation

The vertical positions of each mark on the staff indicated which pitch or pitches it represented. (Pitches were derived from a musical mode.) Although the four-line staff has remained in use until the present day for plainchant, for other types of music, staffs with differing numbers of lines have been used at various times and places for various instruments. The modern five-line staff was first adopted in France and became almost universal by the 16th century (although the use of staves with other numbers of lines was still widespread well into the 17th century).

Notation had developed far enough to notate melody, but there was still no system for notating rhythm. A mid-13th-century treatise, *De Mensurabili Musica*, explains a set of six rhythmic modes that were in use at the time,[8] although it is not clear how they were formed. These rhythmic modes were all in triple time and rather limited rhythm in chant to 6 different repeating patterns. This was a flaw seen by German music theorist Franco of Cologne and summarised as part of his treatise *Ars cantus mensurabilis* (the art of measured chant, or Mensural notation). He suggested that individual notes could have their own rhythms represented by the shape of the note. Not until the 14th century did something like the present system of fixed note lengths arise. The use of regular measures (bars) became commonplace by the end of the 17th century.

The founder of what is now considered the standard music stave was Guido d'Arezzo,[9] an Italian Benedictine monk who lived from about 991 until after 1033. He taught the use of solmization syllables based on a hymn to Saint John the Baptist, which begins Ut Queant Laxis and was written by the Lombard historian Paul the Deacon. The first stanza is:

1. **Ut** queant laxis
2. **re**sonare fibris,
3. **Mi**ra gestorum
4. **fa**muli tuorum,
5. **Sol**ve polluti
6. **la**bii reatum,
7. **S**ancte **I**ohannes.

Guido used the first syllable of each line, Ut, Re, Mi, Fa, Sol and La, to read notated music in terms of hexachords; they were not note names, and each could, depending on context, be applied to any note. In the 17th century, Ut was changed in most countries except France to the easily singable, "open" syllable Do, said to have been taken from the name of the Italian theorist Giovanni Battista Doni.[10]

2.2 Modern staff notation

Main article: List of musical symbols

Modern music notation originated in European classical music and is now used by musicians of many different genres throughout the world.

An example of modern musical notation: Prelude, Op. 28, No. 7, by Frédéric Chopin

The system uses a five-line staff. Pitch is shown by placement of notes on the staff (sometimes modified by accidentals), and duration is shown with different note values and additional symbols such as dots and ties. Notation is read from left to right, which makes setting music for right-to-left scripts difficult.

A staff (or stave, in British English) of written music generally begins with a clef, which indicates the position of one particular note on the staff. The treble or G clef was originally a letter G and it identifies the second line up on the five line staff as the note G above middle C. The bass or F clef shows the position of the note F below middle C. Notes representing a pitch outside of the scope of the five line staff can be represented using ledger lines, which provide a single note with additional lines and spaces.

Following the clef, the key signature on a staff indicates the key of the piece by specifying that certain notes are flat or sharp throughout the piece, unless otherwise indicated.

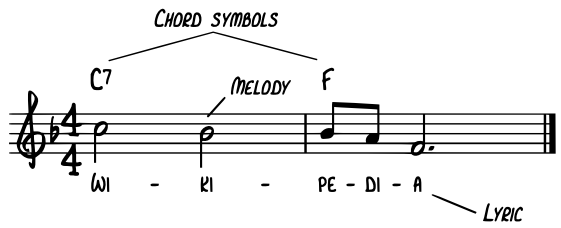
Following the key signature is the time signature. Measures (bars) divide the piece into groups of beats, and the time signatures specify those groupings.

Directions to the player regarding matters such as tempo, dynamics and expression appear above or below the staff.

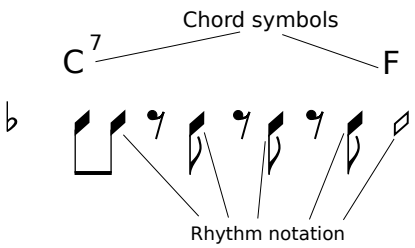
For vocal music, lyrics are written. For short pauses (breaths), retakes (looks like ') are added.

In music for ensembles, a "score" shows music for all players together, while "parts" contain only the music played by an individual musician. A score can be constructed from a complete set of parts and vice versa. The process can be laborious but computer software offers a more convenient and flexible method.

2.2.1 Specialized notation conventions



A lead sheet



A chord chart. Play

- Percussion notation conventions are varied because of the wide range of percussion instruments. Percussion instruments are generally grouped into two categories: pitched and non-pitched. The notation of non-pitched percussion instruments is the more problematic and less standardized.
- Figured bass notation originated in Baroque basso continuo parts. It is also used extensively in accordion notation. The bass notes of the music are conventionally notated, along with numbers and other signs that determine the chords to play. It does not, however, specify the exact pitches of the harmony, leaving that for the performer to improvise.
- A lead sheet specifies only the melody, lyrics and harmony, using one staff with chord symbols placed above and lyrics below. It is used to capture the essential elements of a popular song without specifying how the song should be arranged or performed.
- A chord chart or "chart" contains little or no melodic information at all but provides detailed harmonic and rhythmic information, using slash notation and rhythmic notation. This is the most common kind of written music used by professional session musicians playing jazz or other forms of popular music and is intended primarily for the rhythm section (usually containing piano, guitar, bass and drums).
- Simpler chord charts for songs may contain only the chord changes, placed above the lyrics where they occur. Such charts depend on prior knowledge of the melody, and are used as reminders in performance or informal group singing.
- The shape note system is found in some church hymnals, sheet music, and song books, especially in the Southern United States. Instead of the customary elliptical note head, note heads of various shapes are used to show the position of the note on the major scale. Sacred Harp is one of the most popular tune books using shape notes.

2.3 Notation in various countries

2.3.1 India

Main article: Swaralipi

The Indian scholar and musical theorist Pingala (c. 200

Indian music, early 20th century

BC), in his *Chanda Sutra*, used marks indicating long and short syllables to indicate meters in Sanskrit poetry.

In the notation of Indian rāga, a solfege-like system called sargam is used. As in Western solfege, there are names for the seven basic pitches of a major scale (Shadja, Rishabh, Gandhar, Madhyam, Pancham, Dhaivat and Nishad, usually shortened Sa Re Ga Ma Pa Dha Ni). The tonic of any scale is named Sa, and the dominant Pa. Sa is fixed in any scale, and Pa is fixed at a fifth above it (a Pythagorean fifth rather than an equal-tempered fifth). These two notes are known as achala swar ('fixed notes'). Each of the other five notes, Re, Ga, ma, Dha and Ni, can take a 'regular' (shuddha) pitch, which is equivalent to its pitch in a standard major scale (thus, shuddha Re, the second degree of the scale, is a whole-step higher than Sa), or an altered pitch, either a half-step above or half-step below the shuddha pitch. Re, Ga, Dha and Ni all have

altered partners that are a half-step lower (Komal-"flat") (thus, komal Re is a half-step higher than Sa). Ma has an altered partner that is a half-step higher (teevra-"sharp") (thus, tivra Ma is an augmented fourth above Sa). Re, Ga, ma, Dha and Ni are called vikrut swar ('movable notes'). In the written system of Indian notation devised by Ravi Shankar, the pitches are represented by Western letters. Capital letters are used for the achala swar, and for the higher variety of all the vikrut swar. Lowercase letters are used for the lower variety of the vikrut swar.

Other systems exist for non-twelve-tone equal temperament and non-Western music, such as the Indian *Swaralipi*.

2.3.2 Russia

Further information: Znamenny chant

In Byzantium and Russia, sacred music was notated with special 'hooks and banners'. (See "Byzantine Empire" above.)

2.3.3 China

Main article: Chinese musical notation

The earliest known examples of text referring to music

Chinese Guqin notation, 1425

in China are inscriptions on musical instruments found in the Tomb of Marquis Yi of Zeng (d. 433 B.C.). Sets of 41 chimestones and 65 bells bore lengthy inscriptions concerning pitches, scales, and transposition. The bells still sound the pitches that their inscriptions refer to. Although no notated musical compositions were found, the inscriptions indicate that the system was sufficiently advanced to allow for musical notation. Two systems of pitch nomenclature existed, one for relative pitch and one for absolute pitch. For relative pitch, a solmization system was used.[11]

The tablature of the guqin is unique and complex; the older form is composed of written words describing how to play a melody step-by-step using the plain language of the time, i.e. Descriptive Notation (Classical Chinese); the newer form, composed of bits of Chinese characters put together to indicate the method of play is called Prescriptive Notation. Rhythm is only vaguely indicated in terms of phrasing. Tablatures for the qin are collected in what is called qinpu.

Gongche notation used Chinese characters for the names of the scale.

The jianpu system of notation (probably an adaptation of a French Galin-Paris-Cheve system) had gained widespread acceptance by 1900. It uses a movable do system, with the numbers 1,2,3,4,5,6,7 standing for do, re, mi, fa, sol, la, si. Dots above or below a numeral indicate the octave of the note it represents. Key signatures, barlines, and time signatures are also employed. Many symbols from Western standard notation, such as bar lines, time signatures, accidentals, tie and slur, and the expression markings are also used. The number of dashes following a numeral represents the number of crotchets (quarter notes) by which the note extends. The number of underlines is analogous to the number of flags or beams on notes or rests in standard notation.

2.3.4 Korea

Jeongganbo (or Chong Gan Bo, □□□, □□□) is traditional Korean musical notation system introduced by Sejong the Great and known as the first musical notation system that is able to represent durations of notes in the Eastern. Among various kinds of Korean traditional music, Jeongganbo targets a particular genre, Jeongak(□□, □□).

2.3.5 Japan

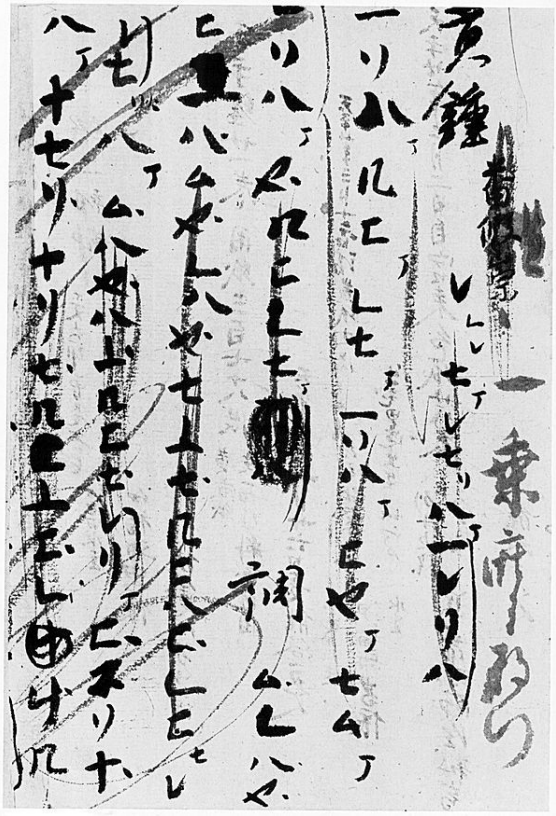
Further information: Shakuhachi musical notation

Japanese music is highly diversified, and therefore requires various systems of notation. In Japanese shakuhachi music, for example, glissandos and timbres are often more significant than distinct pitches, whereas taiko notation focuses on discrete strokes.

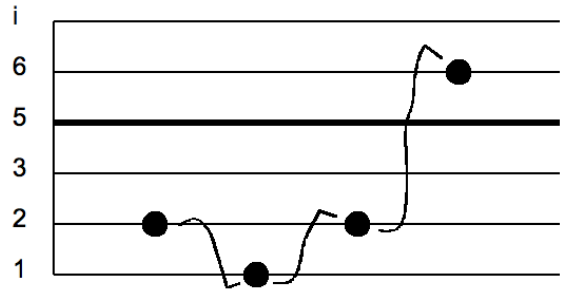
2.3.6 Indonesia

Main article: Gamelan notation

Notation plays a relatively minor role in the oral traditions of Indonesia. However, in Java and Bali, several systems were devised beginning at the end of the 19th century, initially for archival purposes. Today the most widespread are cipher notations ("not angka" in the broadest sense) in which the pitches are represented with some subset of the numbers 1 to 7, with 1 corresponding to either highest note of a particular octave, as in Sundanese gamelan, or lowest, as in the kepatihan notation of Javanese gamelan. Notes in the ranges outside

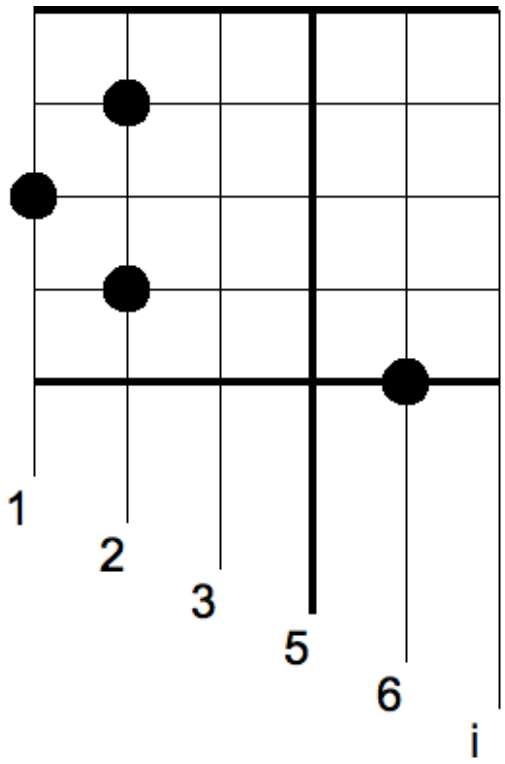


Tempyō Biwa Fu 天平琵琶譜 *(circa 738 AD), musical notation for Biwa. (Shōsōin, at Nara, Japan)*



A short melody in slendro notated using the Surakarta method.[12]

the central octave are represented with one or more dots above or below the each number. For the most part, these cipher notations are mainly used to notate the skeletal melody (the balungan) and vocal parts (gerongan), although transcriptions of the elaborating instrument variations are sometimes used for analysis and teaching. Drum parts are notated with a system of symbols largely based on letters representing the vocables used to learn and remember drumming patterns; these symbols are typically laid out in a grid underneath the skeletal melody for a specific or generic piece. The symbols used for drum notation (as well as the vocables represented) are highly variable from place to place and performer to performer. In addition to these current systems, two older notations used a kind of staff: the Solonese script could capture the flexible rhythms of the pesinden with a squiggle on a



The same notated using the Yogyakarta method or 'chequered notation'.[12]

The same notated using Kepatihan notation.[12]

The same approximated using Western notation.[12] *Play*

horizontal staff, while in Yogyakarta a ladder-like vertical staff allowed notation of the balungan by dots and also included important drum strokes. In Bali, there are a few books published of Gamelan gender wayang pieces, employing alphabetical notation in the old Balinese script.

Composers and scholars both Indonesian and foreign have also mapped the slendro and pelog tuning systems of gamelan onto the western staff, with and without various symbols for microtones. The Dutch composer Ton

de Leeuw also invented a three line staff for his composition *Gending*. However, these systems do not enjoy widespread use.

In the second half of the twentieth century, Indonesian musicians and scholars extended cipher notation to other oral traditions, and a diatonic scale cipher notation has become common for notating western-related genres (church hymns, popular songs, and so forth). Unlike the cipher notation for gamelan music, which uses a "fixed Do" (that is, 1 always corresponds to the same pitch, within the natural variability of gamelan tuning), Indonesian diatonic cipher notation is "moveable-Do" notation, so scores must indicate which pitch corresponds to the number 1 (for example, "1=C").

2.4 Other systems and practices

2.4.1 Cipher notation

In many cultures, including Chinese (jianpu or gongche), Indonesian (kepatihan), and Indian (sargam), the "sheet music" consists primarily of the numbers, letters or native characters representing notes in order. Those different systems are collectively known as cipher notations. The numbered notation, or numerical notation, is an example, so are letter notation and Solfège if written in musical sequence.

2.4.2 Solfège

Main article: Solfège

Solfège is a way of assigning syllables to names of the musical scale. In order, they are today: *Do Re Mi Fa Sol La Ti Do′* (for the octave). The classic variation is: *Do Re Mi Fa Sol La Si Do′* . The first Western system of functional names for the musical notes was introduced by Guido of Arezzo (c.991 – after 1033), using the beginning syllables of the first six musical lines of the Latin hymn Ut queant laxis. The original sequence was *Ut Re Mi Fa Sol La*, where each verse started a scale note higher. "Ut" later became "Do". The equivalent syllables used in Indian music are: *Sa Re Ga Ma Pa Dha Ni*. See also: solfège, sargam, Kodály hand signs. In China Xi is used instead of Ti.

Tonic sol-fa is a type of notation using the initial letters of solfège.

2.4.3 Letter notation

Main article: Letter notation

The notes of the 12-tone scale can be written by their letter names A–G, possibly with a trailing sharp or flat symbol, such as A♯ or B♭. This is the most common way of specifying a note in English speech or written text.

In Northern and Central Europe (e.g., Germany, Austria, Poland, Czech Republic, Slovakia, Hungary, Slovenia, Denmark, Iceland, Norway, Finland, Estonia, Latvia, and the Netherlands—and with diminishing frequency in Sweden), the letter system used is slightly different for historical reasons. In these countries' languages, the note called simply B in English (i.e., B♮) is called H, and the note B♭ is named B. (The C chromatic scale is thus: C C♯ D D♯ E F F♯ G G♯ A B H C). Also, the endings -is (for sharp) and -es/-s (for flat) are used. The note a semitone above C is either "Cis" or "Des", and A♭ is "As". Often this is also used in writing (instead of using the sharp or flat symbol), especially in flowing text. Another difference is that these languages often write the notes in lower case, e.g., ais, c, d, es, fis. Lower case denotes the minor, upper case denotes the major, so A = Amaj and a = Amin.

2.4.4 Tablature

Main article: Tablature

Tablature was first used in the Middle Ages for organ music and later in the Renaissance for lute music.[13] In most lute tablatures, a staff is used, but instead of pitch values, the lines of the staff represent the strings of the instrument. The frets to finger are written on each line, indicated by letters or numbers. Rhythm is written separately with one or another variation of standard note values indicating the duration of the slowest moving part. Few seem to have remarked on the fact that tablature combines in one notation system both the physical and technical requirements of play (the lines and symbols on them and in relation to each other representing the actual performance actions) with the unfolding of the music itself (the lines of tablature taken horizontally represent the actual temporal unfolding of the music). In later periods, lute and guitar music was written with standard notation. Tablature caught interest again in the late 20th century for popular guitar music and other fretted instruments, being easy to transcribe and share over the internet in ASCII format. Websites like Tablature#OLGA.net[14] (currently off-line pending legal disputes) have archives of text-based popular music tablature.

2.4.5 Klavar notation

Main article: Klavarskribo

2.4.6 Piano roll based notations

Some chromatic systems have been created taking advantage of the layout of black and white keys of the standard piano keyboard. The "staff" is most widely referred to as "piano roll", created by extending the black and white piano keys. The best known application of the "piano roll staff" is in digital music producing computer software such as Cubase, GarageBand, etc. Piano sheet music (traditional music notes on the piano roll staff) have also been printed and published, for the claimed benefit of visual matching of music notes and the piano keys to play. Examples are *klavarskribo*, *Hao Staff* and *Ambrose Piano Tabs*.

2.4.7 12-note non-equal temperament

Sometimes the pitches of music written in just intonation are notated with the frequency ratios, while Ben Johnston devised a system that represents just intonation with traditional western notation, with the addition of accidentals that indicate the cents to lower or raise a pitch.

2.4.8 Chromatic staff notations

Over the past three centuries, hundreds of music notation systems have been proposed as alternatives to traditional western music notation. Many of these systems seek to improve upon traditional notation by using a "chromatic staff" in which each of the 12 pitch classes has its own unique place on the staff. Examples are the *Ailler-Brennink* notation, Jacques-Daniel Rochat's *Dodeka*[15] system, Tom Reed's *Twinline* notation, Russell Ambrose's *Ambrose Piano Tabs*,[16] Paul Morris' *TwinNote*,[17] John Keller's *Express Stave*, and José A. Sotorrio's *Bilinear Music Notation*. These notation systems do not require the use of standard key signatures, accidentals, or clef signs. They also represent interval relationships more consistently and accurately than traditional notation. The Music Notation Project (formerly known as the Music Notation Modernization Association) has a website with information on many of these notation systems.[18]

2.4.9 Graphic notation

Main article: Graphic notation

The term 'graphic notation' refers to the contemporary use of non-traditional symbols and text to convey information about the performance of a piece of music. Practitioners include Christian Wolff, Earle Brown, Anthony Braxton, John Cage, Morton Feldman, Krzysztof Penderecki, Cornelius Cardew, and Roger Reynolds. See *Notations*, edited by John Cage and Alison Knowles, ISBN 0-685-14864-5.

2.4.10 Simplified Music Notation

Main article: Simplified music notation

Simplified Music Notation is an alternative form of musical notation designed to make sight-reading easier. It is based on classical staff notation, but incorporates sharps and flats into the shape of the noteheads. Notes such as double sharps and double flats are written at the pitch they are actually played at, but preceded by symbols called *history signs* that show they have been transposed. The notation was designed to help people who struggle with sight-reading, including those who suffer from working memory impairments, dyslexia and other learning difficulties.

2.4.11 Modified Stave Notation

Main article: Modified Stave Notation

Modified Stave Notation (MSN) is an alternative way of notating music for people who cannot easily read ordinary musical notation even if it is enlarged. Such users include those with visual impairments and those who are dyslexic.

2.4.12 Parsons code

Main article: Parsons code

Parsons code is used to encode music so that it can be easily searched. This style is designed for individuals with no musical background.

2.4.13 Braille music

Main article: Braille music

Braille music is a complete, well developed, and internationally accepted musical notation system that has symbols and notational conventions quite independent of print music notation. It is linear in nature, similar to a printed language and different from the two-dimensional nature of standard printed music notation. To a degree Braille music resembles musical markup languages[19] such as MusicXML[20] or NIFF.

2.4.14 Integer notation

In integer notation, or the integer model of pitch, all pitch classes and intervals between pitch classes are designated using the numbers 0 through 11. It is not used to notate music for performance, but is a common analytical

and compositional tool when working with chromatic music, including twelve-tone technique, serial, or otherwise atonal music.

2.4.15 Rap notation

The standard form of rap notation is the "flow diagram", where rappers line up their lyrics underneath "beat numbers".[21] Hip-hop scholars also make use of the same flow diagrams that rappers use: the books *How to Rap* and *How to Rap 2* extensively use the diagrams to explain rap's triplets, flams, rests, rhyme schemes, runs of rhyme, and breaking rhyme patterns, among other techniques.[22] Similar systems are used by musicologists Adam Krims in his book *Rap Music and the Poetics of Identity*[23] and Kyle Adams in his work on rap's flow.[24] As rap revolves around a strong 4/4 beat,[25] with certain syllables aligned to the beat, all the notational systems have a similar structure: they all have four beat numbers at the top of the diagram, so that syllables can be written in-line with the beat.[25]

2.5 Music notation on computer

Main article: Scorewriter

Many computer programs have been developed for creating music notation (called *scorewriters* or *music notation software*). Music may also be stored in various digital file formats for purposes other than graphic notation output.

2.6 Perspectives of musical notation in composition and musical performance

According to Philip Tagg and Richard Middleton, musicology and to a degree European-influenced musical practice suffer from a 'notational centricity', a methodology slanted by the characteristics of notation.[26]

2.7 Patents

In some countries, new musical notations can be patented. In the United States, for example, about 90 patents have been issued for new notation systems. The earliest patent, U.S. Patent 1,383 was published in 1839.

(57) **ABSTRACT**

A method of music notation with 7 spaces for the notes of the C major scale, with the remaining notes of the 12 tone scale overlapping these spaces. 5 staff lines per octave can be used to show the position of the accidental notes. Distinct colors are assigned to the 12 notes of the scale. Two distinct groups of colors are used, one for coloring the C major notes, the other for coloring the remaining 5 notes of the scale. The spaces representing Cs are marked with a colored shape at the left of the staff and shaded horizontally across the page. The notes are shapes whose width is proportional to their durations. Aids are placed above and below the staff to indicate hand and finger movements. Assembly kits with visual aids are provided. The colors can be used on conventional notation.

Chapter 3

Pitch (music)

In musical notation, the different vertical positions of notes indicate different ***pitches****. Play top & Play bottom*

Pitch is a perceptual property that allows the ordering of sounds on a frequency-related scale.[1] Pitches are compared as "higher" and "lower" in the sense associated with musical melodies,[2] which require sound whose frequency is clear and stable enough to distinguish from noise.[3] Pitch is a major auditory attribute of musical tones, along with duration, loudness, and timbre.[4]

Pitch may be quantified as a frequency, but pitch is not a purely objective physical property; it is a subjective psychoacoustical attribute of sound. Historically, the study of pitch and pitch perception has been a central problem in psychoacoustics, and has been instrumental in forming and testing theories of sound representation, processing, and perception in the auditory system.[5]

3.1 Perception of pitch

3.1.1 Pitch and frequency

Pitch is an auditory sensation in which a listener assigns musical tones to relative positions on a musical scale based primarily on the frequency of vibration.[6] Pitch is closely related to frequency, but the two are not equivalent. Frequency is an objective, scientific concept, whereas pitch is subjective. Sound waves themselves do not have pitch, and their oscillations can be measured to obtain a frequency. It takes a human mind to map the internal quality of pitch. Pitches are usually quantified as frequencies in cycles per second, or hertz, by comparing sounds with pure tones, which have periodic, sinusoidal waveforms. Complex and aperiodic sound waves can often be assigned a pitch by this method.[7][8][9]

According to the American National Standards Institute, pitch is the auditory attribute of sound according to which sounds can be ordered on a scale from low to high. Since pitch is such a close proxy for frequency, it is almost entirely determined by how quickly the sound wave is making the air vibrate and has almost nothing to do with the intensity, or amplitude, of the wave. That is, "high" pitch means very rapid oscillation, and "low" pitch corresponds to slower oscillation. Despite that, the idiom relating vertical height to sound pitch is shared by most languages.[10] At least in English, it is just one of many deep conceptual metaphors that involve up/down. The exact etymological history of the musical sense of high and low pitch is still unclear. There is evidence that humans do actually perceive that the source of a sound is slightly higher or lower in vertical space when the sound frequency is increased or decreased.[10]

In most cases, the pitch of complex sounds such as speech and musical notes corresponds very nearly to the repetition rate of periodic or nearly-periodic sounds, or to the reciprocal of the time interval between repeating similar events in the sound waveform.[8][9]

The pitch of complex tones can be ambiguous, meaning that two or more different pitches can be perceived, depending upon the observer.[5] When the actual fundamental frequency can be precisely determined through physical measurement, it may differ from the perceived pitch because of overtones, also known as upper partials, harmonic or otherwise. A complex tone composed of two sine waves of 1000 and 1200 Hz may sometimes be heard as up to three pitches: two spectral pitches at 1000 and 1200 Hz, derived from the physical frequencies of the pure tones, and the combination tone at 200 Hz, corresponding to the repetition rate of the waveform. In a situation like this, the percept at 200 Hz is commonly referred to as the missing fundamental, which is often the greatest common divisor of the frequencies present.[11]

Pitch depends to a lesser degree on the sound pressure level (loudness, volume) of the tone, especially at frequencies below 1,000 Hz and above 2,000 Hz. The pitch of lower tones gets lower as sound pressure increases. For instance, a tone of 200 Hz that is very loud seems one semitone lower in pitch than if it is just barely audible. Above 2,000 Hz, the pitch gets higher as the sound gets louder.[12]

3.1.2 Theories of pitch perception

Theories of pitch perception try to explain how the physical sound and specific physiology of the auditory system work together to yield the experience of pitch. In general, pitch perception theories can be divided into place coding and temporal coding. Place theory holds that the perception of pitch is determined by the place of maximum excitation on the basilar membrane.

A place code, taking advantage of the tonotopy in the auditory system, must be in effect for the perception of high frequencies, since neurons have an upper limit on how fast they can phase-lock their action potentials.[6] However, a purely place-based theory cannot account for the accuracy of pitch perception in the low and middle frequency ranges.

Temporal theories offer an alternative that appeals to the temporal structure of action potentials, mostly the phase-locking and mode-locking of action potentials to frequencies in a stimulus. The precise way this temporal structure helps code for pitch at higher levels is still debated, but the processing seems to be based on an autocorrelation of action potentials in the auditory nerve.[13] However, it has long been noted that a neural mechanism that may accomplish a delay—a necessary operation of a true autocorrelation—has not been found.[6] At least one model shows that a temporal delay is unnecessary to produce an autocorrelation model of pitch perception, appealing to phase shifts between cochlear filters;[14] however, earlier work has shown that certain sounds with a prominent peak in their autocorrelation function do not elicit a corresponding pitch percept,[15][16] and that certain sounds without a peak in their autocorrelation function nevertheless elicit a pitch.[17][18] To be a more complete model, autocorrelation must therefore apply to signals that represent the output of the cochlea, as via auditory-nerve interspike-interval histograms.[16] Some theories of pitch perception hold that pitch has inherent octave ambiguities, and therefore is best decomposed into a pitch *chroma*, a periodic value around the octave, like the note names in western music, and a pitch *height*, which may be ambiguous, indicating which octave the pitch may be in.[5]

3.1.3 Just-noticeable difference

The *just-noticeable difference (jnd)* (the threshold at which a change is perceived) depends on the tone's frequency content. Below 500 Hz, the jnd is about 3 Hz for sine waves, and 1 Hz for complex tones; above 1000 Hz, the jnd for sine waves is about 0.6% (about 10 cents).[19] The **jnd** is typically tested by playing two tones in quick succession with the listener asked if there was a difference in their pitches.[12] The **jnd** becomes smaller if the two tones are played simultaneously as the listener is then able to discern beat frequencies. The total number of perceptible pitch steps in the range of human hearing is about 1,400; the total number of notes in the equal-tempered scale, from 16 to 16,000 Hz, is 120.[12]

3.1.4 Aural illusions

The relative perception of pitch can be fooled, resulting in *aural illusions*. There are several of these, such as the tritone paradox, but most notably the Shepard scale, where a continuous or discrete sequence of specially formed tones can be made to sound as if the sequence continues ascending or descending forever.

3.2 Definite and indefinite pitch

Not all musical instruments make notes with a clear pitch. The unpitched percussion instrument (a class of percussion instrument) does not produce particular pitches. A sound or note of **definite pitch** is one where a listener can possibly (or relatively easily) discern the pitch. Sounds with definite pitch have harmonic frequency spectra or close to harmonic spectra.[12]

A sound generated on any instrument produces many modes of vibration that occur simultaneously. A listener hears numerous frequencies at once. The vibration with the lowest frequency is called the *fundamental frequency*; the other frequencies are *overtones*.[20] *Harmonics* are an important class of overtones with frequencies that are integer multiples of the fundamental. Whether or not the higher frequencies are integer multiples, they are collectively called the partials, referring to the different parts that make up the total spectrum.

A sound or note of **indefinite pitch** is one that a listener finds impossible or relatively difficult to identify as to pitch. Sounds with indefinite pitch do not have harmonic spectra or have altered harmonic spectra a characteristic known as inharmonicity.

It is still possible for two sounds of indefinite pitch to clearly be higher or lower than one another. For instance, a snare drum sounds higher pitched than a bass drum though both have indefinite pitch, because its sound contains higher frequencies. In other words, it is possible and often easy to roughly discern the relative pitches of

two sounds of indefinite pitch, but sounds of indefinite pitch do not neatly correspond to any specific pitch. A special type of pitch often occurs in free nature when sound reaches the ear of an observer directly from the source, and also after reflecting off a sound-reflecting surface. This phenomenon is called *repetition pitch,* because the addition of a true repetition of the original sound to itself is the basic prerequisite.

3.3 Pitch standards and Standard pitch

Main article: Concert pitch

A pitch standard (also Concert pitch) is the conventional pitch reference a group of musical instruments are tuned to for a performance. Concert pitch may vary from ensemble to ensemble, and has varied widely over musical history.

Standard pitch is a more widely accepted convention. The **A** above middle C is usually set at 440 Hz (often written as “A = 440 Hz" or sometimes “A440”), although other frequencies, such as 442 Hz, are also often used as variants. Another standard pitch, the so-called “Baroque pitch”, has been set in the 20th century as A = 415 Hz, exactly an equal tempered semitone lower than A440, in order to facilitate transposition between them.

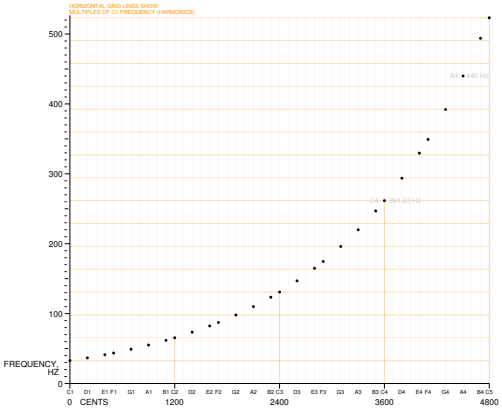
Transposing instruments have their origin in the variety of pitch standards. In modern times, they conventionally have their parts transposed into different keys from voices and other instruments (and even from each other). As a result, musicians need a way to refer to a particular pitch in an unambiguous manner when talking to each other.

For example, the most common type of clarinet or trumpet, when playing a note written in their part as C, sounds a pitch that is called B♭ on a non-transposing instrument like a violin (which indicates that at one time these wind instruments played at a standard pitch a tone lower than violin pitch). In order to refer to that pitch unambiguously, one may call it *concert B♭*, meaning, "...the pitch that someone playing a non-transposing instrument like a violin calls B♭.”

3.4 Labeling pitches

For a comprehensive list of frequencies of musical notes, see Scientific pitch notation and Frequencies of notes.
Pitches are labeled using:

- Letters, as in Helmholtz pitch notation
- A combination of letters and numbers—as in scientific pitch notation, where notes are labelled upwards from C0, the 16 Hz C



Note frequencies, four-octave C major diatonic scale, starting with C1.

- Number that represent the frequency in hertz (Hz), the number of cycles per second

For example, one might refer to the A above middle C as *a'*, *A4*, or *440 Hz*. In standard Western equal temperament, the notion of pitch is insensitive to “spelling": the description “G4 double sharp” refers to the same pitch as *A4*; in other temperaments, these may be distinct pitches. Human perception of musical intervals is approximately logarithmic with respect to fundamental frequency: the perceived interval between the pitches “A220” and “A440” is the same as the perceived interval between the pitches *A440* and *A880*. Motivated by this logarithmic perception, music theorists sometimes represent pitches using a numerical scale based on the logarithm of fundamental frequency. For example, one can adopt the widely used MIDI standard to map fundamental frequency, f, to a real number, p, as follows

$$p = 69 + 12 \times \log_2 \left(\frac{f}{440 \text{ Hz}} \right)$$

This creates a linear pitch space in which octaves have size 12, semitones (the distance between adjacent keys on the piano keyboard) have size 1, and A440 is assigned the number 69. (See Frequencies of notes.) Distance in this space corresponds to musical intervals as understood by musicians. An equal-tempered semitone is subdivided into 100 cents. The system is flexible enough to include “microtones” not found on standard piano keyboards. For example, the pitch halfway between C (60) and C♯ (61) can be labeled 60.5.

3.5 Scales

The relative pitches of individual notes in a scale may be determined by one of a number of tuning systems. In the west, the twelve-note chromatic scale is the most common method of organization, with equal temperament now the

most widely used method of tuning that scale. In it, the pitch ratio between any two successive notes of the scale is exactly the twelfth root of two (or about 1.05946). In well-tempered systems (as used in the time of Johann Sebastian Bach, for example), different methods of musical tuning were used. Almost all of these systems have one interval in common, the octave, where the pitch of one note is double the frequency of another. For example, if the A above middle C is 440 Hz, the A an octave above that is 880 Hz .

3.6 Other musical meanings of pitch

In atonal, twelve tone, or musical set theory a “pitch” is a specific frequency while a pitch class is all the octaves of a frequency. In many analytic discussions of atonal and post-tonal music, pitches are named with integers because of octave and enharmonic equivalency (for example, in a serial system, C♯ and D♭ are considered the same pitch, while C4 and C5 are functionally the same, one octave apart).

Discrete pitches, rather than continuously variable pitches, are virtually universal, with exceptions including "tumbling strains"[21] and “indeterminate-pitch chants”.[22] Gliding pitches are used in most cultures, but are related to the discrete pitches they reference or embellish.[23]

[2] Plack, Christopher J.; Andrew J. Oxenham, Richard R. Fay, eds. (2005). *Pitch: Neural Coding and Perception*. Springer. ISBN 0-387-23472-1. For the purposes of this book we decided to take a conservative approach, and to focus on the relationship between pitch and musical melodies. Following the earlier ASA definition, we define pitch as 'that attribute of sensation whose variation is associated with musical melodies.' Although some might find this too restrictive, an advantage of this definition is that it provides a clear procedure for testing whether or not a stimulus evokes a pitch, and a clear limitation on the range of stimuli that we need to consider in our discussions.

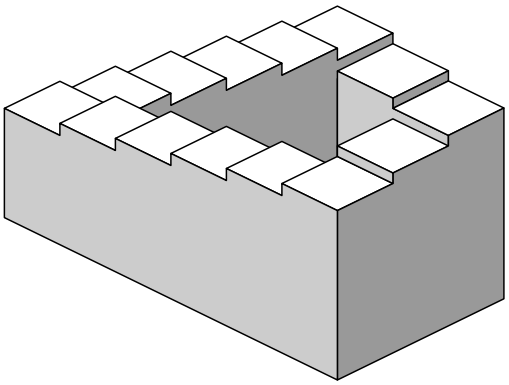
Chapter 4

Pitch circularity



Penrose stairs, visual metaphor for pitch circularity[1]

Pitch circularity is a fixed series of tones that appear to ascend or descend endlessly in pitch.

Pitch is often defined as extending along a one-dimensional continuum from high to low, as can be experienced by sweeping one's hand up or down a piano keyboard. This continuum is known as pitch height. However pitch also varies in a circular fashion, known as pitch class: as one plays up a keyboard in semitone steps, C, C♯, D, D♯, E, F, F♯, G, G♯, A, A♯ and B sound in succession, followed by C again, but one octave higher. Due to the fact that the octave is the most consonant interval after the unison, tones that stand in octave relation, and are so of the same pitch class, have a certain perceptual equivalence—all Cs sound more alike to other Cs than to any other pitch class, as do all D♯s, and so on; this creates the auditory equivalent of a Barber's pole.

Researchers have demonstrated that by creating banks of tones whose note names are clearly defined perceptually but whose perceived heights are ambiguous, one can create scales that appear to ascend or descend endlessly in pitch. Roger Shepard achieved this ambiguity of height by creating banks of complex tones, with each tone composed only of components that stood in octave relationship. In other words, the components of the complex tone C consisted only of Cs, but in different octaves, and the components of the complex tone F♯ consisted only of F♯s, but in different octaves.[2] When such complex tones are played in semitone steps the listener perceives a scale that appears to ascend endlessly in pitch. Jean-Claude Risset achieved the same effect using gliding tones instead, so that a single tone appeared to glide up or down endlessly in pitch.[3] Circularity effects based on this principle have been produced in orchestral music and electronic music, by having multiple instruments playing simultaneously in different octaves.

Normann et al.[4] showed that pitch circularity can be created using a bank of single tones; here the relative amplitudes of the odd and even harmonics of each tone are manipulated so as to create ambiguities of height. A different algorithm that creates ambiguities of pitch height by manipulating the relative amplitudes of the odd and even harmonics, was developed by Diana Deutsch and colleagues. [5] Using this algorithm, gliding tones that appear to ascend or descend endlessly are also produced. This development has led to the intriguing possibility that, using this new algorithm, one might transform banks of natural instrument samples so as to produce tones that sound like those of natural instruments but still have the property of circularity. This development opens up new avenues for music composition and performance.[6]

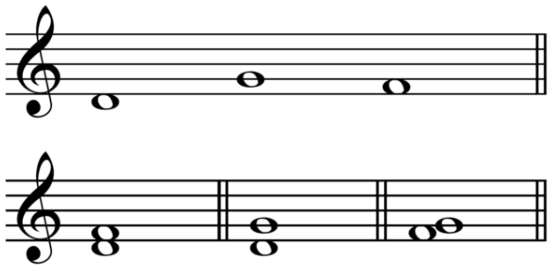
Chapter 5

Interval (music)

For albums named Intervals, see Interval (disambiguation).

In music theory, an **interval** is the difference between



Melodic and harmonic intervals. Play

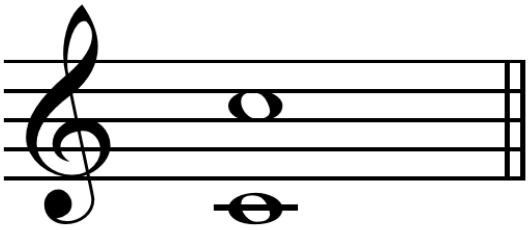
two pitches.[1] An interval may be described as **horizontal**, **linear**, or **melodic** if it refers to successively sounding tones, such as two adjacent pitches in a melody, and **vertical** or **harmonic** if it pertains to simultaneously sounding tones, such as in a chord.[2][3]

In Western music, intervals are most commonly differences between notes of a diatonic scale. The smallest of these intervals is a semitone. Intervals smaller than a semitone are called microtones. They can be formed using the notes of various kinds of non-diatonic scales. Some of the very smallest ones are called commas, and describe small discrepancies, observed in some tuning systems, between enharmonically equivalent notes such as C♯ and D♭. Intervals can be arbitrarily small, and even imperceptible to the human ear.

In physical terms, an interval is the ratio between two sonic frequencies. For example, any two notes an octave apart have a frequency ratio of 2:1. This means that successive increments of pitch by the same interval result in an exponential increase of frequency, even though the human ear perceives this as a linear increase in pitch. For this reason, intervals are often measured in cents, a unit derived from the logarithm of the frequency ratio.

In Western music theory, the most common naming scheme for intervals describes two properties of the interval: the quality (perfect, major, minor, augmented, diminished) and number (unison, second, third, etc.). Examples include the minor third or perfect fifth. These names describe not only the difference in semitones between the upper and lower notes, but also how the interval is spelled. The importance of spelling stems from the historical practice of differentiating the frequency ratios of enharmonic intervals such as G-G♯ and G-A♭.[4]

5.1 Size



Example: Perfect octave on C in equal temperament and just intonation: 2/1 = 1200 cents. Play

The size of an interval (also known as its width or height) can be represented using two alternative and equivalently valid methods, each appropriate to a different context: frequency ratios or cents.

5.1.1 Frequency ratios

Main article: Interval ratio

The size of an interval between two notes may be measured by the ratio of their frequencies. When a musical instrument is tuned using a just intonation tuning system, the size of the main intervals can be expressed by small-integer ratios, such as 1:1 (unison), 2:1 (octave), 3:2 (perfect fifth), 4:3 (perfect fourth), 5:4 (major third), 6:5 (minor third). Intervals with small-integer ratios are often called *just intervals*, or *pure intervals*. To most people, just intervals sound consonant, that is, pleasant and well tuned.

Most commonly, however, musical instruments are nowadays tuned using a different tuning system, called 12-tone

equal temperament, in which the main intervals are typically perceived as consonant, but none is justly tuned and as consonant as a just interval, except for the unison (1:1) and octave (2:1). As a consequence, the size of most equal-tempered intervals cannot be expressed by small-integer ratios, although it is very close to the size of the corresponding just intervals. For instance, an equal-tempered fifth has a frequency ratio of $2^{7/12}$:1, approximately equal to 1.498:1, or 2.997:2 (very close to 3:2). For a comparison between the size of intervals in different tuning systems, see section Size in different tuning systems.

5.1.2 Cents

Main article: Cent (music)

The standard system for comparing interval sizes is with cents. The cent is a logarithmic unit of measurement. If frequency is expressed in a logarithmic scale, and along that scale the distance between a given frequency and its double (also called octave) is divided into 1200 equal parts, each of these parts is one cent. In twelve-tone equal temperament (12-TET), a tuning system in which all semitones have the same size, the size of one semitone is exactly 100 cents. Hence, in 12-TET the cent can be also defined as one hundredth of a semitone.

Mathematically, the size in cents of the interval from frequency f_1 to frequency f_2 is

$$n = 1200 \cdot \log_2 \left(\frac{f_2}{f_1} \right).$$

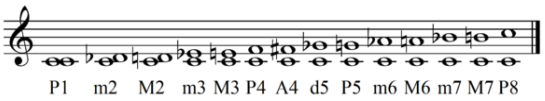
5.2 Main intervals

The table shows the most widely used conventional names for the intervals between the notes of a chromatic scale. A perfect unison (also known as perfect prime)[5] is an interval formed by two identical notes. Its size is zero cents. A semitone is any interval between two adjacent notes in a chromatic scale, a whole tone is an interval spanning two semitones (for example, a major second), and a tritone is an interval spanning three tones, or six semitones (for example, an augmented fourth).[6] Rarely, the term ditone is also used to indicate an interval spanning two whole tones (for example, a major third), or more strictly as a synonym of major third.

Intervals with different names may span the same number of semitones, and may even have the same width. For instance, the interval from D to F♯ is a major third, while that from D to G♭ is a diminished fourth. However, they both span 4 semitones. If the instrument is tuned so that the 12 notes of the chromatic scale are equally spaced (as in equal temperament), these intervals will also have the same width. Namely, all semitones will have a width of 100 cents, and all intervals spanning 4 semitones will be 400 cents wide.

The names listed here cannot be determined by counting semitones alone. The rules to determine them are explained below. Other names, determined with different naming conventions, are listed in a separate section. Intervals smaller than one semitone (commas or microtones) and larger than one octave (compound intervals) are introduced below.

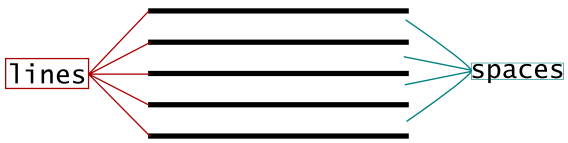
5.3 Interval number and quality



Main intervals from C. Play

In Western music theory, an interval is named according to its *number* (also called *diatonic number*) and *quality*. For instance, *major third* (or **M3**) is an interval name, in which the term *major* (**M**) describes the quality of the interval, and *third* (**3**) indicates its number.

5.3.1 Number



Staff, with staff positions indicated.

Fifth from C to G in the A♭ major scale.

The number of an interval is the number of staff positions it encompasses. Both lines and spaces (see figure) are counted, including the positions of both notes forming the interval. For instance, the interval C–G is a fifth (denoted **P5**) because the notes from C to G occupy five consecutive staff positions, including the positions of C and G. The table and the figure above show intervals with numbers ranging from 1 (e.g., **P1**) to 8 (e.g., **P8**). Intervals with larger numbers are called compound intervals.

There is a one-to-one correspondence between staff positions and diatonic-scale degrees (the notes of a diatonic

scale).[9] This means that interval numbers can be also determined by counting diatonic scale degrees, rather than staff positions, provided that the two notes which form the interval are drawn from a diatonic scale. Namely, C–G is a fifth because in any diatonic scale that contains C and G, the sequence from C to G includes five notes. For instance, in the A♭-major diatonic scale, the five notes are C–D♭–E♭–F–G (see figure). This is not true for all kinds of scales. For instance, in a chromatic scale, the notes from C to G are eight (C–C♯–D–D♯–E–F–F♯–G). This is the reason interval numbers are also called *diatonic numbers*, and this convention is called *diatonic numbering*.

If one takes away any accidentals from the notes which form an interval, by definition the notes do not change their staff positions. As a consequence, any interval has the same interval number as the corresponding natural interval, formed by the same notes without accidentals. For instance, the intervals C–G♯ (spanning 8 semitones) and C♯–G (spanning 6 semitones) are fifths, like the corresponding natural interval C–G (7 semitones).

Interval numbers do not represent exactly interval widths. For instance, the interval C–D is a second, but D is only one staff position, or diatonic-scale degree, above C. Similarly, C–E is a third, but E is only two staff positions above C, and so on. As a consequence, joining two intervals always yields an interval number one less than their sum. For instance, the intervals C–E and E–G are thirds, but joined together they form a fifth (C–G), not a sixth. Similarly, a stack of three thirds, such as C–E, E–G, and G–B, is a seventh (C–B), not a ninth.

The rule to determine the diatonic number of a compound interval (an interval larger than one octave), based on the diatonic numbers of the simple intervals from which it is built is explained in a separate section.

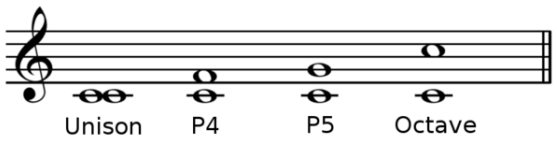
5.3.2 Quality

	C and …	D and …	E and …	F and …	G and …	A and …	B and …
C	P1						
D	M2	P1					
E	M3	M2	P1				
F	P4	m3	m2	P1			
G	P5	P4	m3	M2	P1		
A	M6	P5	P4	M3	M2	P1	
B	M7	M6	P5	A4 (TT)	M3	M2	P1
c	P8	m7	m6	P5	P4	m3	m2
d		P8	m7	M6	P5	P4	m3
e			P8	M7	M6	P5	P4
f				P8	m7	m6	d5 (TT)
g					P8	m7	m6
a						P8	m7
b							P8

Intervals formed by the notes of a C major diatonic scale.

The name of any interval is further qualified using the terms **perfect** (**P**), major (**M**), minor (**m**), augmented (**A**), and diminished (**d**). This is called its *interval quality*. It is possible to have doubly diminished and doubly augmented intervals, but these are quite rare, as they occur only in chromatic contexts. The quality of a compound interval is the quality of the simple interval on which it is based.

Perfect



Perfect intervals on C. PU , P4 , P5 , P8 .

Perfect intervals are so-called because they were traditionally considered perfectly consonant,[10] although in Western classical music the perfect fourth was sometimes regarded as a less than perfect consonance, when its function was contrapuntal. Conversely, minor, major, augmented or diminished intervals are typically considered to be less consonant, and were traditionally classified as mediocre consonances, imperfect consonances, or dissonances.[10]

Within a diatonic scale[9] all unisons (**P1**) and octaves (**P8**) are perfect. Most fourths and fifths are also perfect (**P4** and **P5**), with five and seven semitones respectively. There's one occurrence of a fourth and a fifth which are not perfect, as they both span six semitones: an augmented fourth (**A4**), and its inversion, a diminished fifth (**d5**). For instance, in a C-major scale, the **A4** is between F and B, and the **d5** is between B and F (see table).

By definition, the inversion of a perfect interval is also perfect. Since the inversion does not change the pitch of the two notes, it hardly affects their level of consonance (matching of their harmonics). Conversely, other kinds of intervals have the opposite quality with respect to their inversion. The inversion of a major interval is a minor interval, the inversion of an augmented interval is a diminished interval.

Major/minor

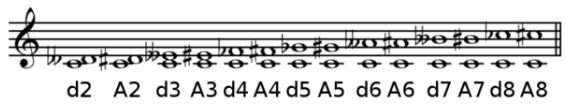
Major and minor intervals on C. m2 , M2 , m3 , M3 , m6 , M6 , m7 , M7

As shown in the table, a diatonic scale[9] defines seven intervals for each interval number, each starting from a different note (seven unisons, seven seconds, etc.). The intervals formed by the notes of a diatonic scale are called diatonic. Except for unisons and octaves, the diatonic intervals with a given interval number always occur in two

sizes, which differ by one semitone. For example, six of the fifths span seven semitones. The other one spans six semitones. Four of the thirds span three semitones, the others four. If one of the two versions is a perfect interval, the other is called either diminished (i.e. narrowed by one semitone) or augmented (i.e. widened by one semitone). Otherwise, the larger version is called major, the smaller one minor. For instance, since a 7-semitone fifth is a perfect interval (**P5**), the 6-semitone fifth is called "diminished fifth" (**d5**). Conversely, since neither kind of third is perfect, the larger one is called "major third" (**M3**), the smaller one "minor third" (**m3**).

Within a diatonic scale,[9] unisons and octaves are always qualified as perfect, fourths as either perfect or augmented, fifths as perfect or diminished, and all the other intervals (seconds, thirds, sixths, sevenths) as major or minor.

Augmented/diminished



Augmented and diminished intervals on C. d2 , A2 , d3 , A3 , d4 , A4 , d5 , A5 , d6 , A6 , d7 , A7 , d8 , A8

Augmented and diminished intervals are so called because they exceed or fall short of either a perfect interval, or a major/minor pair by one semitone, while having the same interval number (i.e., encompassing the same number of staff positions). For instance, an augmented third such as C–E♯ spans five semitones, exceeding a major third (C–E) by one semitone, while a diminished third such as C♯–E♭ spans two semitones, falling short of a minor third (C–E♭) by one semitone.

Except for the above-mentioned augmented fourth (**A4**) and diminished fifth (**d5**), augmented and diminished intervals do not appear in diatonic scales[9] (see table).

5.3.3 Example

Neither the number, nor the quality of an interval can be determined by counting semitones alone. As explained above, the number of staff positions must be taken into account as well.

For example, as shown in the table below, there are four semitones between A♭ and B♯, between A and C♯, between A and D♭, and between A♯ and E𝄫, but

- A♭–B♯ is a second, as it encompasses two staff positions (A, B), and it is doubly augmented, as it exceeds a major second (such as A-B) by two semitones.
- A–C♯ is a third, as it encompasses three staff positions (A, B, C), and it is major, as it spans 4 semitones.
- A–D♭ is a fourth, as it encompasses four staff positions (A, B, C, D), and it is diminished, as it falls short of a perfect fourth (such as A-D) by one semitone.
- A♯-E𝄫 is a fifth, as it encompasses five staff positions (A, B, C, D, E), and it is triply diminished, as it falls short of a perfect fifth (such as A-E) by three semitones.

5.4 Shorthand notation

Intervals are often abbreviated with a **P** for perfect, **m** for minor, **M** for major, **d** for diminished, **A** for augmented, followed by the interval number. The indication M and P are often omitted. The octave is P8, and a unison is usually referred to simply as "a unison" but can be labeled P1. The tritone, an augmented fourth or diminished fifth is often **TT**. The interval qualities may be also abbreviated with **perf**, **min**, **maj**, **dim**, **aug**. Examples:

- m2 (or min2): minor second,
- M3 (or maj3): major third,
- A4 (or aug4): augmented fourth,
- d5 (or dim5): diminished fifth,
- P5 (or perf5): perfect fifth.

5.5 Inversion

Main article: Inversion (music)

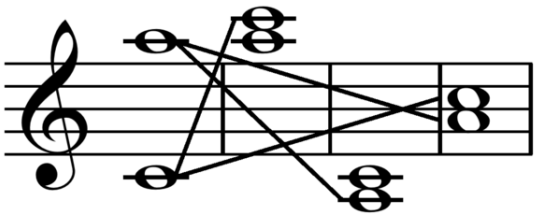
A simple interval (i.e., an interval smaller than or equal

Interval inversions

to an octave) may be inverted by raising the lower pitch an octave, or lowering the upper pitch an octave. For example, the fourth from a lower C to a higher F may be inverted to make a fifth, from a lower F to a higher C.

There are two rules to determine the number and quality of the inversion of any simple interval:[11]

1. The interval number and the number of its inversion always add up to nine (4 + 5 = 9, in the example just given).



Major 13th (compound Major 6th) inverts to a minor 3rd by moving the bottom note up two octaves, the top note down two octaves, or both notes one octave

2. The inversion of a major interval is a minor interval, and vice versa; the inversion of a perfect interval is also perfect; the inversion of an augmented interval is a diminished interval, and vice versa; the inversion of a doubly augmented interval is a doubly diminished interval, and vice versa.

For example, the interval from C to the E♭ above it is a minor third. By the two rules just given, the interval from E♭ to the C above it must be a major sixth.

Since compound intervals are larger than an octave, "the inversion of any compound interval is always the same as the inversion of the simple interval from which it is compounded."[12]

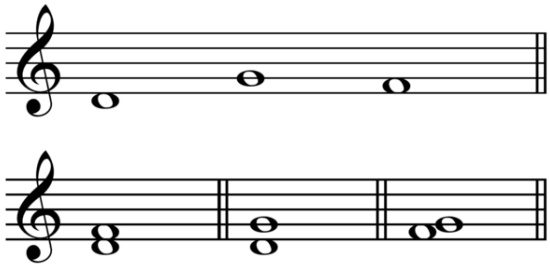
For intervals identified by their ratio, the inversion is determined by reversing the ratio and multiplying by 2. For example, the inversion of a 5:4 ratio is an 8:5 ratio.

For intervals identified by an integer number of semitones, the inversion is obtained by subtracting that number from 12.

Since an interval class is the lower number selected among the interval integer and its inversion, interval classes cannot be inverted.

5.6 Classification

Intervals can be described, classified, or compared with each other according to various criteria.



Melodic and harmonic intervals. Play

5.6.1 Melodic and harmonic

Main articles: Harmony and Melody

An interval can be described as

- Vertical or harmonic if the two notes sound simultaneously
- Horizontal, linear, or melodic if they sound successively.[2]

5.6.2 Diatonic and chromatic

Main article: Diatonic and chromatic

In general,

- A *diatonic interval* is an interval formed by two notes of a diatonic scale.
- A *chromatic interval* is a non-diatonic interval formed by two notes of a chromatic scale.

Ascending and descending chromatic scale on C Play .

The table above depicts the 56 diatonic intervals formed by the notes of the C major scale (a diatonic scale). Notice that these intervals, as well as any other diatonic interval, can be also formed by the notes of a chromatic scale.

The distinction between diatonic and chromatic intervals is controversial, as it is based on the definition of diatonic scale, which is variable in the literature. For example, the interval B–E♭ (a diminished fourth, occurring in the harmonic C-minor scale) is considered diatonic if the harmonic minor scales are considered diatonic as well.[13] Otherwise, it is considered chromatic. For further details, see the main article.

By a commonly used definition of diatonic scale[9] (which excludes the harmonic minor and melodic minor scales), all perfect, major and minor intervals are diatonic. Conversely, no augmented or diminished interval is diatonic, except for the augmented fourth and diminished fifth.

The A♭-major scale. Play

The distinction between diatonic and chromatic intervals may be also sensitive to context. The above-mentioned

56 intervals formed by the C-major scale are sometimes called *diatonic to C major*. All other intervals are called *chromatic to C major*. For instance, the perfect fifth A♭–E♭ is chromatic to C major, because A♭ and E♭ are not contained in the C major scale. However, it is diatonic to others, such as the A♭ major scale.

5.6.3 Consonant and dissonant

Main article: Consonance and dissonance

Consonance and dissonance are relative terms that refer to the stability, or state of repose, of particular musical effects. Dissonant intervals are those that cause tension, and desire to be *resolved* to consonant intervals.

These terms are relative to the usage of different compositional styles.

- In the Middle Ages, only the unison, octave, perfect fourth, and perfect fifth were considered consonant harmonically.
- In 15th- and 16th-century usage, perfect fifths and octaves, and major and minor thirds and sixths were considered harmonically consonant, and all other intervals dissonant, including the perfect fourth, which by 1473 was described (by Johannes Tinctoris) as dissonant, except between the upper parts of a vertical sonority—for example, with a supporting third below ("6-3 chords").[14] In the common practice period, it makes more sense to speak of consonant and dissonant chords, and certain intervals previously thought to be dissonant (such as minor sevenths) became acceptable in certain contexts. However, 16th-century practice continued to be taught to beginning musicians throughout this period.
- Hermann von Helmholtz (1821–1894) defined a harmonically consonant interval as one in which the two pitches have an upper partial (an overtone) in common[15] (specifically *excluding* the seventh harmonic). This essentially defines all seconds and sevenths as dissonant, and the above thirds, fourths, fifths, and sixths as consonant.
- Pythagoras defined a hierarchy of consonance based on how small the numbers are that express the ratio. 20th-century composer and theorist Paul Hindemith's system has a hierarchy with the same results as Pythagoras's, but defined by fiat rather than by interval ratios, to better accommodate equal temperament, all of whose intervals (except the octave) would be dissonant using acoustical methods.
- David Cope (1997) suggests the concept of **interval strength**,[16] in which an interval's strength, consonance, or stability is determined by its approximation to a lower and stronger, or higher and weaker, position in the harmonic series. See also: Lipps–Meyer law.
- #Interval root

All of the above analyses refer to vertical (simultaneous) intervals.

5.6.4 Simple and compound

Simple and compound major third. Play

A simple interval is an interval spanning at most one octave (see Main intervals above). Intervals spanning more than one octave are called compound intervals, as they can be obtained by adding one or more octaves to a simple interval (see below for details).[17]

5.6.5 Steps and skips

Main article: Steps and skips

Linear (melodic) intervals may be described as *steps* or *skips*. A *step*, or *conjunct motion*,[18] is a linear interval between two consecutive notes of a scale. Any larger interval is called a *skip* (also called a *leap*), or *disjunct motion*.[18] In the diatonic scale,[9] a step is either a minor second (sometimes also called *half step*) or major second (sometimes also called *whole step*), with all intervals of a minor third or larger being skips.

For example, C to D (major second) is a step, whereas C to E (major third) is a skip.

More generally, a step is a smaller or narrower interval in a musical line, and a skip is a wider or larger interval, with the categorization of intervals into steps and skips is determined by the tuning system and the pitch space used.

Melodic motion in which the interval between any two consecutive pitches is no more than a step, or, less strictly, where skips are rare, is called *stepwise* or *conjunct* melodic motion, as opposed to *skipwise* or *disjunct* melodic motions, characterized by frequent skips.

5.6.6 Enharmonic intervals

Main article: Enharmonic

Two intervals are considered to be *enharmonic*, or *en-*

Enharmonic tritones: A4 = d5 on C Play .

harmonically equivalent, if they both contain the same pitches spelled in different ways; that is, if the notes in the two intervals are themselves enharmonically equivalent. Enharmonic intervals span the same number of semitones.

For example, the four intervals listed in the table below are all enharmonically equivalent, because the notes F♯ and G♭ indicate the same pitch, and the same is true for A♯ and B♭. All these intervals span four semitones.

When played on a piano keyboard, these intervals are indistinguishable as they are all played with the same two keys, but in a musical context the diatonic function of the notes incorporated is very different.

5.7 Minute intervals

Pythagorean comma on C. Play . The note depicted as lower on the staff (B♯+++) is slightly higher in pitch (than C♮).

Main articles: Comma (music) and Microtone

There are also a number of minute intervals not found in the chromatic scale or labeled with a diatonic function, which have names of their own. They may be described as microtones, and some of them can be also classified as commas, as they describe small discrepancies, observed in some tuning systems, between enharmonically equivalent notes. In the following list, the interval sizes in cents are approximate.

- A *Pythagorean comma* is the difference between twelve justly tuned perfect fifths and seven octaves. It is expressed by the frequency ratio 531441:524288 (23.5 cents).
- A *syntonic comma* is the difference between four justly tuned perfect fifths and two octaves plus a major third. It is expressed by the ratio 81:80 (21.5 cents).
- A *septimal comma* is 64:63 (27.3 cents), and is the difference between the Pythagorean or 3-limit "7th" and the "harmonic 7th".
- A *diesis* is generally used to mean the difference between three justly tuned major thirds and one octave. It is expressed by the ratio 128:125 (41.1 cents). However, it has been used to mean other small intervals: see diesis for details.
- A *diaschisma* is the difference between three octaves and four justly tuned perfect fifths plus two justly tuned major thirds. It is expressed by the ratio 2048:2025 (19.6 cents).
- A *schisma* (also skhisma) is the difference between five octaves and eight justly tuned fifths plus one justly tuned major third. It is expressed by the ratio 32805:32768 (2.0 cents). It is also the difference between the Pythagorean and syntonic commas. (A schismic major third is a schisma different from a just major third, eight fifths down and five octaves up, F♭ in C.)
- A *kleisma* is the difference between six minor thirds and one *tritave* or *perfect twelfth* (an octave plus a perfect fifth), with a frequency ratio of 15625:15552 (8.1 cents) (Play).
- A *septimal kleisma* is six major thirds up, five fifths down and one octave up, with ratio 225:224 (7.7 cents).
- A *quarter tone* is half the width of a semitone, which is half the width of a whole tone. It is equal to exactly 50 cents.

5.8 Compound intervals

Simple and compound major third. Play

A compound interval is an interval spanning more than one octave.[17] Conversely, intervals spanning at most one octave are called simple intervals (see Main intervals above).

In general, a compound interval may be defined by a sequence or "stack" of two or more simple intervals of any

kind. For instance, a major tenth (two staff positions above one octave), also called *compound major third*, spans one octave plus one major third.

Any compound interval can be always decomposed into one or more octaves plus one simple interval. For instance, a major seventeenth can be decomposed into two octaves and one major third, and this is the reason why it is called a compound major third, even when it is built by adding up four fifths.

The diatonic number DN_c of a compound interval formed from n simple intervals with diatonic numbers DN_1, DN_2, ..., DN_n, is determined by:

$$DN_c = 1+(DN_1-1)+(DN_2-1)+...+(DN_n-1),$$

which can also be written as:

$$DN_c = DN_1 + DN_2 + ... + DN_n - (n-1),$$

The quality of a compound interval is determined by the quality of the simple interval on which it is based. For instance, a compound major third is a major tenth (1+(8–1)+(3–1) = 10), or a major seventeenth (1+(8–1)+(8–1)+(3–1) = 17), and a compound perfect fifth is a perfect twelfth (1+(8–1)+(5–1) = 12) or a perfect nineteenth (1+(8–1)+(8–1)+(5–1) = 19). Notice that two octaves are a fifteenth, not a sixteenth (1+(8–1)+(8–1) = 15). Similarly, three octaves are a twenty-second (1+3*(8–1) = 22), and so on.

5.8.1 Main compound intervals

It is also worth mentioning here the major seventeenth (28 semitones), an interval larger than two octaves which can be considered a multiple of a perfect fifth (7 semitones) as it can be decomposed into four perfect fifths (7 * 4 = 28 semitones), or two octaves plus a major third (12 + 12 + 4 = 28 semitones). Intervals larger than a major seventeenth seldom need to be spoken of, most often being referred to by their compound names, for example “two octaves plus a fifth”[19] rather than “a 19th”.

5.9 Intervals in chords

Main articles: Chord (music) and Chord names and symbols (jazz and pop music)

Chords are sets of three or more notes. They are typically defined as the combination of intervals starting from a common note called the root of the chord. For instance a major triad is a chord containing three notes defined by the root and two intervals (major third and perfect fifth). Sometimes even a single interval (dyad) is considered to be a chord.[20] Chords are classified based on the quality and number of the intervals which define them.

5.9.1 Chord qualities and interval qualities

The main chord qualities are: major, minor, augmented, diminished, half-diminished, and dominant. The symbols used for chord quality are similar to those used for interval quality (see above). In addition, **+** or **aug** is used for augmented, ° or **dim** for diminished, ø for half diminished, and **dom** for dominant (the symbol **–** alone is not used for diminished).

5.9.2 Deducing component intervals from chord names and symbols

The main rules to decode chord *names or symbols* are summarized below. Further details are given at Rules to decode chord names and symbols.

1. For 3-note chords (triads), major or minor always refer to the interval of the third above the root note, while augmented and diminished always refer to the interval of the fifth above root. The same is true for the corresponding symbols (e.g., Cm means Cm3, and C+ means C+5). Thus, the terms third and fifth and the corresponding symbols 3 and 5 are typically omitted. This rule can be generalized to all kinds of chords,[21] provided the above-mentioned qualities appear immediately after the root note, or at the beginning of the chord name or symbol. For instance, in the chord symbols Cm and Cm7, m refers to the interval m3, and 3 is omitted. When these qualities do not appear immediately after the root note, or at the beginning of the name or symbol, they should be considered interval qualities, rather than chord qualities. For instance, in Cm/M7 (minor major seventh chord), m is the chord quality and refers to the m3 interval, while M refers to the M7 interval. When the number of an extra interval is specified immediately after chord quality, the quality of that interval may coincide with chord quality (e.g., CM7 = CM/M7). However, this is not always true (e.g., Cm6 = Cm/M6, C+7 = C+/m7, CM11 = CM/P11).[21] See main article for further details.

2. Without contrary information, a major third interval and a perfect fifth interval (major triad) are implied. For instance, a C chord is a C major triad, and the name C minor seventh (Cm7) implies a minor 3rd by rule 1, a perfect 5th by this rule, and a minor 7th by definition (see below). This rule has one exception (see next rule).

3. When the fifth interval is diminished, the third must be minor.[22] This rule overrides rule 2. For instance, Cdim7 implies a diminished 5th by rule 1, a minor

3rd by this rule, and a diminished 7th by definition (see below).

4. Names and symbols which contain only a plain interval number (e.g., "Seventh chord") or the chord root and a number (e.g., "C seventh", or C7) are interpreted as follows:

    - If the number is 2, 4, 6, etc., the chord is a major added tone chord (e.g., C6 = CM6 = Cadd6) and contains, together with the implied major triad, an extra major 2nd, perfect 4th, or major 6th (see names and symbols for added tone chords).
    - If the number is 7, 9, 11, 13, etc., the chord is dominant (e.g., C7 = Cdom7) and contains, together with the implied major triad, one or more of the following extra intervals: minor 7th, major 9th, perfect 11th, and major 13th (see names and symbols for seventh and extended chords).
    - If the number is 5, the chord (technically not a chord in the traditional sense, but a dyad) is a power chord. Only the root, a perfect fifth and usually an octave are played.

The table shows the intervals contained in some of the main chords (**component intervals**), and some of the symbols used to denote them. The interval qualities or numbers in **boldface** font can be deduced from chord name or symbol by applying rule 1. In symbol examples, C is used as chord root.

5.10 Size of intervals used in different tuning systems

In this table, the interval widths used in four different tuning systems are compared. To facilitate comparison, just intervals as provided by 5-limit tuning (see symmetric scale n.1) are shown in **bold** font, and the values in cents are rounded to integers. Notice that in each of the non-equal tuning systems, by definition the width of *each* type of interval (including the semitone) changes depending on the note from which the interval starts. This is the price paid for seeking just intonation. However, for the sake of simplicity, for some types of interval the table shows only one value (the most often observed one).

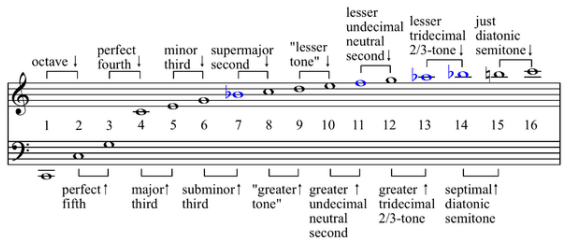
In 1/4-comma meantone, by definition 11 perfect fifths have a size of approximately 697 cents (700−ε cents, where $\varepsilon \approx 3.42$ cents); since the average size of the 12 fifths must equal exactly 700 cents (as in equal temperament), the other one must have a size of about 738 cents (700+11ε, the wolf fifth or diminished sixth); 8 major thirds have size about 386 cents (400−4ε), 4 have size about 427 cents (400+8ε, actually diminished fourths), and their average size is 400 cents. In short, similar differences in width are observed for all interval types, except for unisons and octaves, and they are all multiples of ε (the difference between the 1/4-comma meantone fifth and the average fifth). A more detailed analysis is provided at 1/4-comma meantone Size of intervals. Note that 1/4-comma meantone was designed to produce just major thirds, but only 8 of them are just (5:4, about 386 cents).

The Pythagorean tuning is characterized by smaller differences because they are multiples of a smaller ε ($\varepsilon \approx 1.96$ cents, the difference between the Pythagorean fifth and the average fifth). Notice that here the fifth is wider than 700 cents, while in most meantone temperaments, including 1/4-comma meantone, it is tempered to a size smaller than 700. A more detailed analysis is provided at Pythagorean tuning#Size of intervals.

The 5-limit tuning system uses just tones and semitones as building blocks, rather than a stack of perfect fifths, and this leads to even more varied intervals throughout the scale (each kind of interval has three or four different sizes). A more detailed analysis is provided at 5-limit tuning#Size of intervals. Note that 5-limit tuning was designed to maximize the number of just intervals, but even in this system some intervals are not just (e.g., 3 fifths, 5 major thirds and 6 minor thirds are not just; also, 3 major and 3 minor thirds are wolf intervals).

The above-mentioned symmetric scale 1, defined in the 5-limit tuning system, is not the only method to obtain just intonation. It is possible to construct juster intervals or just intervals closer to the equal-tempered equivalents, but most of the ones listed above have been used historically in equivalent contexts. In particular, the asymmetric version of the 5-limit tuning scale provides a juster value for the minor seventh (9:5, rather than 16:9). Moreover, the tritone (augmented fourth or diminished fifth), could have other just ratios; for instance, 7:5 (about 583 cents) or 17:12 (about 603 cents) are possible alternatives for the augmented fourth (the latter is fairly common, as it is closer to the equal-tempered value of 600 cents). The 7:4 interval (about 969 cents), also known as the harmonic seventh, has been a contentious issue throughout the history of music theory; it is 31 cents flatter than an equal-tempered minor seventh. Some assert the 7:4 is one of the blue notes used in jazz. For further details about reference ratios, see 5-limit tuning#The justest ratios.

In the diatonic system, every interval has one or more *enharmonic equivalents*, such as augmented second for minor third.



Intervals in the harmonic series.

5.11 Interval root

Although intervals are usually designated in relation to their lower note, David Cope[16] and Hindemith[23] both suggest the concept of **interval root**. To determine an interval's root, one locates its nearest approximation in the harmonic series. The root of a perfect fourth, then, is its *top* note because it is an octave of the fundamental in the hypothetical harmonic series. The bottom note of every odd diatonically numbered intervals are the roots, as are the tops of all even numbered intervals. The root of a collection of intervals or a chord is thus determined by the interval root of its strongest interval.

As to its usefulness, Cope[16] provides the example of the final tonic chord of some popular music being traditionally analyzable as a "submediant six-five chord" (added sixth chords by popular terminology), or a first inversion seventh chord (possibly the dominant of the mediant V/iii). According the interval root of the strongest interval of the chord (in first inversion, CEGA), the perfect fifth (C–G), is the bottom C, the tonic.

5.12 Interval cycles

Main articles: Interval cycle and Identity (music)

Interval cycles, "unfold [i.e., repeat] a single recurrent interval in a series that closes with a return to the initial pitch class", and are notated by George Perle using the letter "C", for cycle, with an interval-class integer to distinguish the interval. Thus the diminished-seventh chord would be C3 and the augmented triad would be C4. A superscript may be added to distinguish between transpositions, using 0–11 to indicate the lowest pitch class in the cycle.[24]

5.13 Alternative interval naming conventions

As shown below, some of the above-mentioned intervals have alternative names, and some of them take a specific alternative name in Pythagorean tuning, five-limit tuning, or meantone temperament tuning systems such as quarter-comma meantone. All the intervals with prefix *sesqui-* are justly tuned, and their frequency ratio, shown in the table, is a superparticular number (or epimoric ratio). The same is true for the octave.

Typically, a comma is a diminished second, but this is not always true (for more details, see Alternative definitions of comma). For instance, in Pythagorean tuning the diminished second is a descending interval (524288:531441, or about −23.5 cents), and the Pythagorean comma is its opposite (531441:524288, or about 23.5 cents). 5-limit tuning defines four kinds of comma, three of which meet the definition of diminished second, and hence are listed in the table below. The fourth one, called syntonic comma (81:80) can neither be regarded as a diminished second, nor as its opposite. See Diminished seconds in 5-limit tuning for further details.

Additionally, some cultures around the world have their own names for intervals found in their music. For instance, 22 kinds of intervals, called shrutis, are canonically defined in Indian classical music.

5.13.1 Latin nomenclature

Up to the end of the 18th century, Latin was used as an official language throughout Europe for scientific and music textbooks. In music, many English terms are derived from Latin. For instance, semitone is from Latin *semitonus*.

The prefix semi- is typically used herein to mean "shorter", rather than "half".[25][26][27] Namely, a semitonus, semiditonus, semidiatessaron, semidiapente, semihexachordum, semiheptachordum, or semidiapason, is shorter by one semitone than the corresponding whole interval. For instance, a semiditonus (3 semitones, or about 300 cents) is not half of a ditonus (4 semitones, or about 400 cents), but a ditonus shortened by one semitone. Moreover, in Pythagorean tuning (the most commonly used tuning system up to the 16th century), a semitritonus (d5) is smaller than a tritonus (A4) by one Pythagorean comma (about a quarter of a semitone).

5.14 Pitch-class intervals

Main articles: Interval class and Ordered pitch interval

In post-tonal or atonal theory, originally developed for equal-tempered European classical music written using the twelve-tone technique or serialism, integer notation is often used, most prominently in musical set theory. In this system, intervals are named according to the number of half steps, from 0 to 11, the largest interval class being 6.

In atonal or musical set theory, there are numerous types of intervals, the first being the ordered pitch interval, the

distance between two pitches upward or downward. For instance, the interval from C upward to G is 7, and the interval from G downward to C is −7. One can also measure the distance between two pitches without taking into account direction with the unordered pitch interval, somewhat similar to the interval of tonal theory.

The interval between pitch classes may be measured with ordered and unordered pitch-class intervals. The ordered one, also called directed interval, may be considered the measure upwards, which, since we are dealing with pitch classes, depends on whichever pitch is chosen as 0. For unordered pitch-class intervals, see interval class.[28]

5.15 Generic and specific intervals

Main articles: Specific interval and Generic interval

In diatonic set theory, specific and generic intervals are distinguished. Specific intervals are the interval class or number of semitones between scale steps or collection members, and generic intervals are the number of diatonic scale steps (or staff positions) between notes of a collection or scale.

Notice that staff positions, when used to determine the conventional interval number (second, third, fourth, etc.), are counted including the position of the lower note of the interval, while generic interval numbers are counted excluding that position. Thus, generic interval numbers are smaller by 1, with respect to the conventional interval numbers.

5.15.1 Comparison

5.16 Generalizations and non-pitch uses

Division of the measure/chromatic scale, followed by pitch/time-point series. Play

The term “interval” can also be generalized to other music elements besides pitch. David Lewin's *Generalized Musical Intervals and Transformations* uses interval as a generic measure of distance between time points, timbres, or more abstract musical phenomena.[29][30]

[21] General rule 1 achieves consistency in the interpretation of symbols such as CM7, Cm6, and C+7. Some musicians legitimately prefer to think that, in CM7, M refers to the seventh, rather than to the third. This alternative approach is legitimate, as both the third and seventh are major, yet it is inconsistent, as a similar interpretation is impossible for Cm6 and C+7 (in Cm6, m cannot possibly refer to the sixth, which is major by definition, and in C+7, + cannot refer to the seventh, which is minor). Both approaches reveal only one of the intervals (M3 or M7), and require other rules to complete the task. Whatever is the decoding method, the result is the same (e.g., CM7 is always conventionally decoded as C–E–G–B, implying M3, P5, M7). The advantage of rule 1 is that it has no exceptions, which makes it the simplest possible approach to decode chord quality.
According to the two approaches, some may format CM7 as CM^{7} (general rule 1: M refers to M3), and others as C^{M7} (alternative approach: M refers to M7). Fortunately, even C^{M7} becomes compatible with rule 1 if it is considered an abbreviation of CM^{M7}, in which the first M is omitted. The omitted M is the quality of the third, and is deduced according to rule 2 (see above), consistently with the interpretation of the plain symbol C, which by the same rule stands for CM.

[22] All triads are tertian chords (chords defined by sequences of thirds), and a major third would produce in this case a non-tertian chord. Namely, the diminished fifth spans 6 semitones from root, thus it may be decomposed into a sequence of two minor thirds, each spanning 3 semitones (m3 + m3), compatible with the definition of tertian chord. If a major third were used (4 semitones), this would entail a sequence containing a major second (M3 + M2 = 4 + 2 semitones = 6 semitones), which would not meet the definition of tertian chord.

Chapter 6

Note

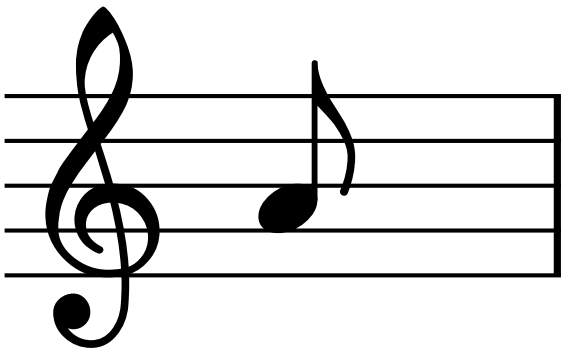
This article is about the musical term. For other uses, see Note (disambiguation).

In music, the term **note** has two primary meanings:

1. A sign used in musical notation to represent the relative duration and pitch of a sound (♪, ♫);
2. A pitched sound itself.

Notes are the "atoms" of much Western music: discretizations of musical phenomena that facilitate performance, comprehension, and analysis.[1]

The term *note* can be used in both generic and specific senses: one might say either "the piece 'Happy Birthday to You' begins with two notes having the same pitch," or "the piece begins with two repetitions of the same note." In the former case, one uses *note* to refer to a specific musical event; in the latter, one uses the term to refer to a class of events sharing the same pitch. (See also: Key signature names and translations).



The note A *or* La

Two notes with fundamental frequencies in a ratio equal to any power of two (e.g. half, twice, or four times) are perceived as very similar. Because of that, all notes with these kinds of relations can be grouped under the same pitch class.

In traditional music theory, most countries in the world use the naming convention Do-Re-Mi-Fa-Sol-La-Si, including for instance Italy, Spain, France, Romania, most Latin American countries, Greece, Bulgaria, Turkey,

Names of some notes without accidentals

Russia, and all the Arabic-speaking or Persian-speaking countries. However, within the English-speaking and Dutch-speaking world, pitch classes are typically represented by the first seven letters of the Latin alphabet (A, B, C, D, E, F and G). A few European countries, including Germany, adopt an almost identical notation, in which H is substituted for B (see below for details).

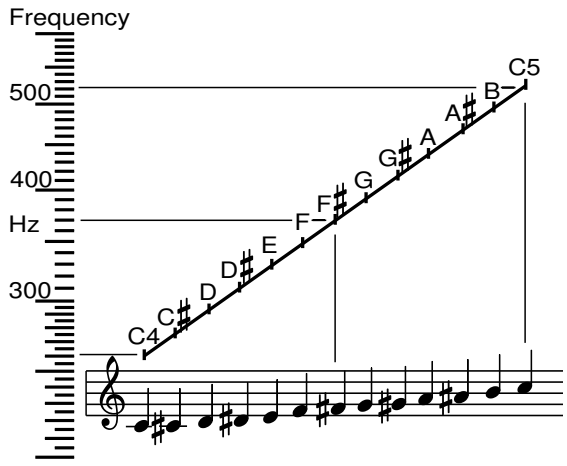
The eighth note, or octave, is given the same name as the first, but has double its frequency. The name octave is also used to indicate the span between a note and another with double frequency. To differentiate two notes that have the same pitch class but fall into different octaves, the system of scientific pitch notation combines a letter name with an Arabic numeral designating a specific octave. For example, the now-standard tuning pitch for most Western music, 440 Hz, is named a′ or A4.

There are two formal systems to define each note and octave, the Helmholtz pitch notation and the Scientific pitch notation.

6.1 Accidentals

Letter names are modified by the accidentals. A sharp ♯ raises a note by a semitone or half-step, and a flat ♭ lowers it by the same amount. In modern tuning a half step has a frequency ratio of $\sqrt[12]{2}$, approximately 1.059. The accidentals are written after the note name: so, for example, F♯ represents F-sharp, B♭ is B-flat.

Additional accidentals are the double-sharp 𝄪, raising the frequency by two semitones, and double-flat 𝄫, lowering it by that amount.



Frequency vs Position on Treble Clef. Each note shown has a frequency of the previous note multiplied by $\sqrt[12]{2}$

In musical notation, accidentals are placed before the note symbols. Systematic alterations to the seven lettered pitches in the scale can be indicated by placing the symbols in the key signature, which then apply implicitly to all occurrences of corresponding notes. Explicitly noted accidentals can be used to override this effect for the remainder of a bar. A special accidental, the natural symbol ♮, is used to indicate an unmodified pitch. Effects of key signature and local accidentals do not cumulate. If the key signature indicates G-sharp, a local flat before a G makes it G-flat (not G natural), though often this type of rare accidental is expressed as a natural, followed by a flat (♮♭) to make this clear. Likewise (and more commonly), a double sharp 𝄪 sign on a key signature with a single sharp ♯ indicates only a double sharp, not a triple sharp.

Assuming enharmonicity, many accidentals will create equivalences between pitches that are written differently. For instance, raising the note B to B♯ is equal to the note C. Assuming all such equivalences, the complete chromatic scale adds five additional pitch classes to the original seven lettered notes for a total of 12 (the 13th note completing the octave), each separated by a half-step.

Notes that belong to the diatonic scale relevant in the context are sometimes called *diatonic notes*; notes that do not meet that criterion are then sometimes called *chromatic notes*.

Another style of notation, rarely used in English, uses the suffix “is” to indicate a sharp and “es” (only “s” after A and E) for a flat, e.g. Fis for F♯, Ges for G♭, Es for E♭. This system first arose in Germany and is used in almost all European countries whose main language is not English, Greek, or a Romance language.

In most countries using these suffixes, the letter H is used to represent what is B natural in English, the letter B is used instead of B♭, and Heses (i.e., H𝄫) is used instead of B𝄫 (not Bes, which would also have fit into the system). Dutch-speakers in Belgium and the Netherlands use the same suffixes, but applied throughout to the notes A to G, so that B, B♭ and B𝄫 have the same meaning as in English, although they are called B, Bes, and Beses instead of B, B flat and B double flat. Denmark also uses H, but uses Bes instead of Heses for B𝄫.

6.2 12-tone chromatic scale

The following chart lists the names used in different countries for the 12 notes of a chromatic scale built on C. The corresponding symbols are shown within parenthesis. Differences between German and English notation are highlighted in **bold** typeface. Although the English and Dutch names are different, the corresponding symbols are identical.

6.3 Note designation in accordance with octave name

The table of each octave and the frequencies for every note of pitch class A is shown below. The traditional (Helmholtz) system centers on the great octave (with capital letters) and small octave (with lower case letters). Lower octaves are named “contra” (with primes before), higher ones “lined” (with primes after). Another system (scientific) suffixes a number (starting with 0, or sometimes −1). In this system A4 is nowadays standardised to 440 Hz, lying in the octave containing notes from C4 (middle C) to B4. The lowest note on most pianos is A0, the highest C8. The MIDI system for electronic musical instruments and computers uses a straight count starting with note 0 for C-1 at 8.1758 Hz up to note 127 for G9 at 12,544 Hz.

6.4 Written notes

A written note can also have a note value, a code that determines the note’s relative duration. In order of halving duration, we have: double note (breve); whole note (semibreve); half note (minim); quarter note (crotchet); eighth note (quaver); sixteenth note (semiquaver). Smaller still are the thirty-second note (demisemiquaver), sixty-fourth note (hemidemisemiquaver), and hundred twenty-eighth note (semihemidemisemiquaver) or 1
2 note, 1
4 note, 1
8 note, 1
16 note, 1
32 note, 1
64 note, and 1
128 note.

When notes are written out in a score, each note is assigned a specific vertical position on a staff position (a line or a space) on the staff, as determined by the clef. Each line or space is assigned a note name. These names are memorized by musicians and allow them to know at a glance the proper pitch to play on their instruments for each note-head marked on the page.

The staff above shows the notes C, D, E, F, G, A, B, C listen and then in reverse order, with no key signature or accidentals.

6.5 Note frequency (hertz)

Main article: Mathematics of musical scales

In all technicality, *music* can be composed of notes at any arbitrary physical frequency. Since the physical causes of music are vibrations of mechanical systems, they are often measured in hertz (Hz), with 1 Hz = one vibration per second. For historical and other reasons, especially in Western music, only twelve notes of fixed frequencies are used. These fixed frequencies are mathematically related to each other, and are defined around the central note, *A4*. The current "standard pitch" or modern "concert pitch" for this note is 440 Hz, although this varies in actual practice (see History of pitch standards).

The note-naming convention specifies a letter, any accidentals, and an octave number. Any note is an integer of half-steps away from middle A (A4). Let this distance be denoted n. If the note is above A4, then n is positive; if it is below A4, then n is negative. The frequency of the note (f) (assuming equal temperament) is then:

$$f = 2^{n/12} \times 440\,\text{Hz}$$

For example, one can find the frequency of C5, the first C above A4. There are 3 half-steps between A4 and C5 (A4 → A♯4 → B4 → C5), and the note is above A4, so n = +3. The note's frequency is:

$$f = 2^{3/12} \times 440\,\text{Hz} \approx 523.2\,\text{Hz}$$

To find the frequency of a note below A4, the value of n is negative. For example, the F below A4 is F4. There are 4 half-steps (A4 → A♭4 → G4 → G♭4 → F4), and the note is below A4, so n = −4. The note's frequency is:

$$f = 2^{-4/12} \times 440\,\text{Hz} \approx 349.2\,\text{Hz}$$

Finally, it can be seen from this formula that octaves automatically yield powers of two times the original frequency, since n is therefore a multiple of 12 (12k, where k is the number of octaves up or down), and so the formula reduces to:

$$f = 2^{12k/12} \times 440\,\text{Hz} = 2^k \times 440\,\text{Hz}$$

yielding a factor of 2. In fact, this is the means by which this formula is derived, combined with the notion of equally-spaced intervals.

The distance of an equally tempered semitone is divided into 100 cents. So 1200 cents are equal to one octave — a frequency ratio of 2:1. This means that a cent is precisely equal to the 1200th root of 2, which is approximately 1.000578.

For use with the MIDI (Musical Instrument Digital Interface) standard, a frequency mapping is defined by:

$$p = 69 + 12 \times \log_2 \frac{f}{440\,\text{Hz}}$$

Where p is the MIDI note number. And in the opposite direction, to obtain the frequency from a MIDI note p, the formula is defined as:

$$f = 2^{(p-69)/12} \times 440\,\text{Hz}$$

For notes in an A440 equal temperament, this formula delivers the standard MIDI note number (p). Any other frequencies fill the space between the whole numbers evenly. This allows MIDI instruments to be tuned very accurately in any microtuning scale, including non-western traditional tunings.

6.6 History of note names

Music notation systems have used letters of the alphabet for centuries. The 6th century philosopher Boethius is known to have used the first fourteen letters of the classical Latin alphabet,

> A-B-C-D-E-F-G-H-I-K-L-M-N-O (the letter J didn't exist until the 16th century)

to signify the notes of the two-octave range that was in use at the time,[6] and which in modern scientific pitch notation is represented as

> A_2-B_2-C_3-D_3-E_3-F_3-G_3-A_3-B_3-C_4-D_4-E_4-F_4-G_4.

Though it is not known whether this was his devising or common usage at the time, this is nonetheless called *Boethian notation*. Although Boethius is the first author

which is known to have used this nomenclature in the literature, the above-mentioned two-octave range was already known five centuries before by Ptolemy, who called it the "perfect system" or "complete system", as opposed to other systems of notes of smaller range, which did not contain all the possible species of octave (i.e., the seven octaves starting from A, B, C, D, E, F, and G).

Following this, the range (or compass) of used notes was extended to three octaves, and the system of repeating letters A-G in each octave was introduced, these being written as lower case for the second octave (a-g) and double lowercase letters for the third (aa-gg). When the range was extended down by one note, to a G, that note was denoted using the Greek G (Γ), gamma. (It is from this that the French word for scale, *gamme* is derived, and the English word gamut, from "Gamma-Ut", the lowest note in Medieval music notation.)

The remaining five notes of the chromatic scale (the black keys on a piano keyboard) were added gradually; the first being B♭, since B was flattened in certain modes to avoid the dissonant tritone interval. This change was not always shown in notation, but when written, B♭ (B-flat) was written as a Latin, round "b", and B♮ (B-natural) a Gothic or "hard-edged" b. These evolved into the modern flat (♭) and natural (♮) symbols respectively. The sharp symbol arose from a barred b, called the "cancelled b".

In parts of Europe, including Germany, the Czech Republic, Slovakia, Poland, Hungary, Norway, Denmark, Serbia, Croatia, Finland, Iceland and Sweden, the Gothic b transformed into the letter H (possibly for *hart*, German for *hard*, or just because the Gothic b resembled an H). Therefore, in German music notation, H is used in lieu of B♮ (B-natural), and B in lieu of B♭ (B-flat). Occasionally, music written in German for international use will use H for B-natural and B^{b} for B-flat (with a modern-script lowercase b instead of a flat sign). Since a Bes or B♭ in Northern Europe (i.e. a B𝄫 elsewhere) is both rare and unorthodox (more likely to be expressed as Heses), it is generally clear what this notation means.

In Italian, Portuguese, Spanish, French, Romanian, Greek, Russian, Mongolian, Flemish, Persian, Arabic, Hebrew, Bulgarian and Turkish notation the notes of scales are given in terms of Do-Re-Mi-Fa-Sol-La-Si rather than C-D-E-F-G-A-B. These names follow the original names reputedly given by Guido d'Arezzo, who had taken them from the first syllables of the first six musical phrases of a Gregorian Chant melody *Ut queant laxis*, which began on the appropriate scale degrees. These became the basis of the solfege system. "Do" later replaced the original "Ut" for ease of singing (most likely from the beginning of *Dominus*, Lord), though "Ut" is still used in some places. "Si" or "Ti" was added as the seventh degree (from *Sancte Johannes*, St. John, to whom the hymn is dedicated). The use of 'Si' versus 'Ti' varies regionally.

The two notation systems most commonly used nowadays are the Helmholtz pitch notation system and the Scientific pitch notation system. As shown in the table above, they both include several octaves, each starting from C rather than A. The reason is that the most commonly used scale in Western music is the major scale, and the sequence C-D-E-F-G-A-B (the C-major scale) is the simplest example of a major scale. Indeed, it is the only major scale which can be obtained using natural notes (the white keys on the piano keyboard), and typically the first musical scale taught in music schools.

In a newly developed system, primarily in use in the United States, notes of scales become independent to the music notation. In this system the natural symbols C-D-E-F-G-A-B refer to the absolute notes, while the names Do-Re-Mi-Fa-So-La-Ti are relativized and show only the relationship between pitches, where Do is the name of the base pitch of the scale, Re is the name of the second pitch, etc. The idea of so-called movable-do, originally suggested by John Curwen in the 19th century, was fully developed and involved into a whole educational system by Zoltán Kodály in the middle of the 20th century, which system is known as the Kodály Method or Kodály Concept.

Chapter 7

Semitone

This article is about the musical interval. For the printing method, see halftone.

A **semitone**, also called a **half step** or a **half tone**,[1] is

Minor second Play .

the smallest musical interval commonly used in Western tonal music,[2] and it is considered the most dissonant[3] when sounded harmonically. It is defined as the interval between two adjacent notes in a 12-tone scale (e.g. from C to C♯). This implies that its size is exactly or approximately equal to 100 cents, a twelfth of an octave.

In a 12-note approximately equally divided scale, any interval can be defined in terms of an appropriate number of semitones (e.g. a whole tone or major second is 2 semitones wide, a major third 4 semitones, and a perfect fifth 7 semitones.

In music theory, a distinction is made[4] between a **diatonic semitone**, or **minor second** (an interval encompassing two staff positions, e.g. from C to D♭) and a **chromatic semitone** or **augmented unison** (an interval between two notes at the same staff position, e.g. from C to C♯). These are enharmonically equivalent when twelve-tone equal temperament is used, but are not the same thing in meantone temperament, where the diatonic semitone is distinguished from and larger than the chromatic semitone (augmented unison.) See Interval (music)#Number for more details about this terminology.

In twelve-tone equal temperament all semitones are equal in size (100 cents). In other tuning systems, "semitone" refers to a family of intervals that may vary both in size and name. In Pythagorean tuning, seven semitones out of twelve are diatonic, with ratio 256:243 or 90.2 cents (Pythagorean limma), and the other five are chromatic, with ratio 2187:2048 or 113.7 cents (Pythagorean apotome); they differ by the Pythagorean comma of ratio 531441:524288 or 23.5 cents. In quarter-comma meantone, seven of them are diatonic, and 117.1 cents wide, while the other five are chromatic, and 76.0 cents wide; they differ by the lesser diesis of ratio 128:125 or 41.1 cents. 12-tone scales tuned in just intonation typically define three or four kinds of semitones. For instance, Asymmetric five-limit tuning yields chromatic semitones with ratios 25:24 (70.7 cents) and 135:128 (92.2 cents), and diatonic semitones with ratios 16:15 (111.7 cents) and 27:25 (133.2 cents). For further details, see below.

Main article: Anhemitonic scale

The condition of having semitones is called hemitonia; that of having no semitones is anhemitonia. A musical scale or chord containing semitones is called hemitonic; one without semitones is anhemitonic.

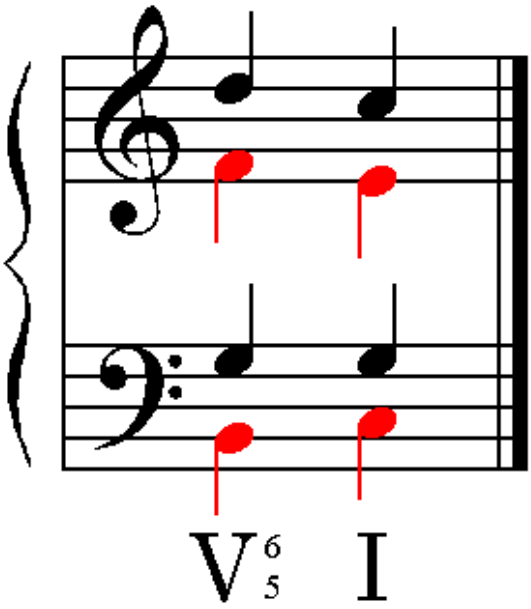
7.1 Minor second

The *minor second* occurs in the major scale, between the third and fourth degree, (*mi* (E) and *fa* (F) in C major), and between the seventh and eighth degree (*ti* (B) and *do* (C) in C major). It is also called the *diatonic semitone* because it occurs between steps in the diatonic scale. The minor second is abbreviated **m2** (or **−2**). Its inversion is the *major seventh* (*M7*, or +*7*).

Listen to a minor second in equal temperament . Here, middle C is followed by D♭, which is a tone 100 cents sharper than C, and then by both tones together.

Melodically, this interval is very frequently used, and is of particular importance in cadences. In the perfect and deceptive cadences it appears as a resolution of the leading-tone to the tonic. In the plagal cadence, it appears as the falling of the subdominant to the mediant. It also occurs in many forms of the imperfect cadence, wherever the tonic falls to the leading-tone.

Harmonically, the interval usually occurs as some form of dissonance or a nonchord tone that is not part of the functional harmony. It may also appear in inversions of a major seventh chord, and in many added tone chords.



The melodic minor second is an integral part of most cadences of the Common practice period.

A harmonic minor second in J.S. Bach's Prelude in C major from the WTC book 1, mm. 7–9. The minor second may be viewed as a suspension of the B *resolving into the following* A minor seventh *chord.*

The opening measures of Frédéric Chopin's "wrong note" Étude.

In unusual situations, the minor second can add a great deal of character to the music. For instance, Frédéric Chopin's Étude Op. 25, No. 5 opens with a melody accompanied by a line that plays fleeting minor seconds. These are used to humorous and whimsical effect, which contrasts with its more lyrical middle section. This eccentric dissonance has earned the piece its nickname: the "wrong note" étude. This kind of usage of the minor second appears in many other works of the Romantic period, such as Modest Mussorgsky's *Ballet of the Unhatched Chicks*. More recently, the music to the movie *Jaws* exemplifies the minor second.

7.2 Augmented unison

Augmented unison on C.

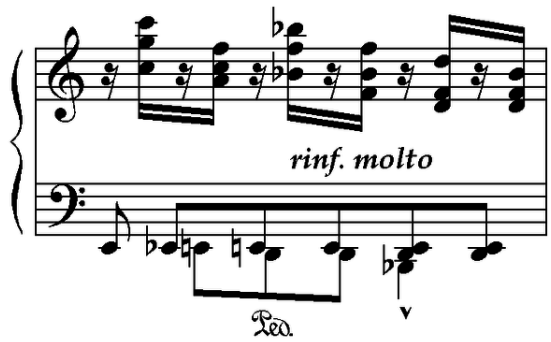
Augmented unisons often appear as a consequence of secondary dominants, such as those in the soprano voice of this sequence from Felix Mendelssohn's Song Without Words *Op. 102 No. 3, mm. 47–49.*

The **augmented unison**, the interval produced by the augmentation, or widening by one-half step, of the perfect unison,[5] does not occur between diatonic scale steps, but instead between a scale step and a chromatic alteration of the same step. It is also called a *chromatic semitone*. The augmented unison is abbreviated **A1**, or **aug 1**. Its inversion is the *diminished octave* (*d8*, or *dim 8*). The augmented unison is also the inversion of the augmented octave, because the interval of the diminished unison does not exist.[6] This is because a unison is always made larger when one note of the interval is changed with an accidental.[7][8]

Melodically, an augmented unison very frequently occurs when proceeding to a chromatic chord, such as a secondary dominant, a diminished seventh chord, or an augmented sixth chord. Its use is also often the consequence of a melody proceeding in semitones, regardless of harmonic underpinning, e.g. **D**, **D♯**, **E**, **F**, **F♯**. (Restricting the notation to only minor seconds is impractical, as the same example would have a rapidly increasing number of accidentals, written enharmonically as **D**, **E♭**, **F♭**, **G𝄫**, **A𝄫𝄫**).

Harmonically, augmented unisons are quite rare in tonal repertoire. In the example to the right, Liszt had written an **E♭** against an **E♮** in the bass. Here **E♭** was preferred to a **D♯** to make the tone's function clear as part of an **F** dominant seventh chord, and the augmented unison is the result of superimposing this harmony upon an **E** pedal point.

In addition to this kind of usage, harmonic augmented unisons are frequently written in modern works involving tone clusters, such as Iannis Xenakis' *Evryali* for piano solo.



Franz Liszt's second Transcendental Etude, measure 63.

7.3 History

The semitone appeared in the music theory of Greek antiquity as part of a diatonic or chromatic tetrachord, and it has always had a place in the diatonic scales of Western music since. The various modal scales of medieval music theory were all based upon this diatonic pattern of tones and semitones.

Though it would later become an integral part of the musical cadence, in the early polyphony of the 11th century this was not the case. Guido of Arezzo suggested instead in his *Micrologus* other alternatives: either proceeding by whole tone from a major second to a unison, or an *occursus* having two notes at a major third move by contrary motion toward a unison, each having moved a whole tone.

"As late as the 13th century the half step was experienced as a problematic interval not easily understood, as the irrational [*sic*] remainder between the perfect fourth and the ditone $\left(\frac{4}{3}/(\frac{9}{8})^2 = \frac{256}{243}\right)$." In a melodic half step, no "tendency was perceived of the lower tone toward the upper, or of the upper toward the lower. The second tone was not taken to be the 'goal' of the first. Instead, the half step was avoided in clausulae because it lacked clarity as an interval." [9]

A dramatic chromatic scale in the opening measures of Luca Marenzio's Solo e pensoso*, ca. 1580. (Play*

However, beginning in the 13th century cadences begin to require motion in one voice by half step and the other a whole step in contrary motion.[9] These cadences would become a fundamental part of the musical language, even to the point where the usual accidental accompanying the minor second in a cadence was often omitted from the written score (a practice known as musica ficta). By the 16th century, the semitone had become a more versatile interval, sometimes even appearing as an augmented unison in very chromatic passages. Semantically, in the 16th century the repeated melodic semitone became associated with weeping, see: passus duriusculus, lament bass, and pianto.

By the Baroque era (1600 to 1750), the tonal harmonic framework was fully formed, and the various musical functions of the semitone were rigorously understood. Later in this period the adoption of well temperaments for instrumental tuning and the more frequent use of enharmonic equivalences increased the ease with which a semitone could be applied. Its function remained similar through the Classical period, and though it was used more frequently as the language of tonality became more chromatic in the Romantic period, the musical function of the semitone did not change.

In the 20th century, however, composers such as Arnold Schoenberg, Béla Bartók, and Igor Stravinsky sought alternatives or extensions of tonal harmony, and found other uses for the semitone. Often the semitone was exploited harmonically as a caustic dissonance, having no resolution. Some composers would even use large collections of harmonic semitones (tone clusters) as a source of cacophony in their music (e.g. the early piano works of Henry Cowell). By now, enharmonic equivalence was a commonplace property of equal temperament, and instrumental use of the semitone was not at all problematic for the performer. The composer was free to write semitones wherever he wished.

7.4 Semitones in different tunings

The exact size of a semitone depends on the tuning system used. Meantone temperaments have two distinct types of semitones, but in the exceptional case of Equal temperament, there is only one. The unevenly distributed well temperaments contain many different semitones. Pythagorean tuning, similar to meantone tuning, has two, but in other systems of just intonation there are many more possibilities.

7.4.1 Meantone temperament

In meantone systems, there are two different semitones. This results because of the break in the circle of fifths that occurs in the tuning system: diatonic semitones derive from a chain of five fifths that does not cross the break, and chromatic semitones come from one that does.

The chromatic semitone is usually smaller than the diatonic. In the common quarter-comma meantone, tuned as a cycle of tempered fifths from E♭ to G♯, the chromatic and diatonic semitones are 76.0 and 117.1 cents wide respectively.

Extended meantone temperaments with more than 12

notes still retain the same two semitone sizes, but there is more flexibility for the musician about whether to use an augmented unison or minor second. 31-tone equal temperament is the most flexible of these, which makes an unbroken circle of 31 fifths, allowing the choice of semitone to be made for any pitch.

7.4.2 Equal temperament

12-tone equal temperament is a form of meantone tuning in which the diatonic and chromatic semitones are exactly the same, because its circle of fifths has no break. Each semitone is equal to one twelfth of an octave. This is a ratio of $2^{1/12}$ (approximately 1.05946), or 100 cents, and is 11.7 cents narrower than the 16:15 ratio (its most common form in just intonation, discussed below).

All diatonic intervals can be expressed as an equivalent number of semitones. For instance a whole tone equals two semitones.

There are many approximations, rational or otherwise, to the equal-tempered semitone. To cite a few:

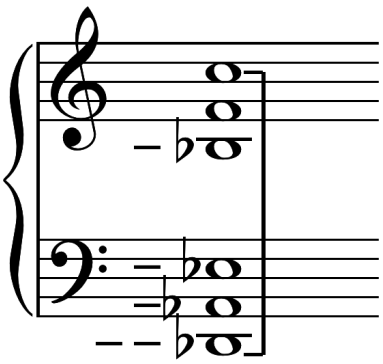
- $18/17 \approx 99.0$cents,
  suggested by Vincenzo Galilei and used by luthiers of the Renaissance,
- $\sqrt[4]{\frac{2}{3-\sqrt{2}}} \approx 100.4$cents,
  suggested by Marin Mersenne as a constructible and more accurate alternative,
- $(139/138)^8 \approx 99.9995$cents,
  used by Julián Carrillo as part of a sixteenth-tone system.

For more examples, see Pythagorean and Just systems of tuning below.

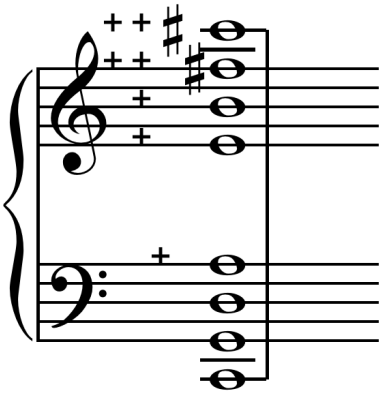
7.4.3 Well temperament

There are many forms of well temperament, but the characteristic they all share is that their semitones are of an uneven size. Every semitone in a well temperament has its own interval (usually close to the equal-tempered version of 100 cents), and there is no clear distinction between a *diatonic* and *chromatic* semitone in the tuning. Well temperament was constructed so that enharmonic equivalence could be assumed between all of these semitones, and whether they were written as a minor second or augmented unison did not effect a different sound. Instead, in these systems, each key had a slightly different sonic color or character, beyond the limitations of conventional notation.

7.4.4 Pythagorean tuning



Pythagorean limma as five descending just perfect fifths from C (the inverse is B+).



Pythagorean apotome as seven just perfect fifths.

Like meantone temperament, Pythagorean tuning is a broken circle of fifths. This creates two distinct semitones, but because Pythagorean tuning is also a form of 3-limit just intonation, these semitones are rational. Also, unlike most meantone temperaments, the chromatic semitone is larger than the diatonic.

The **Pythagorean diatonic semitone** has a ratio of 256/243 (play), and is often called the **Pythagorean limma**. It is also sometimes called the *Pythagorean minor semitone*. It is about 90.2 cents.

$$\frac{256}{243} = \frac{2^8}{3^5} \approx 90.2\text{cents}$$

It can be thought of as the difference between three octaves and five just fifths, and functions as a diatonic semitone in a Pythagorean tuning.

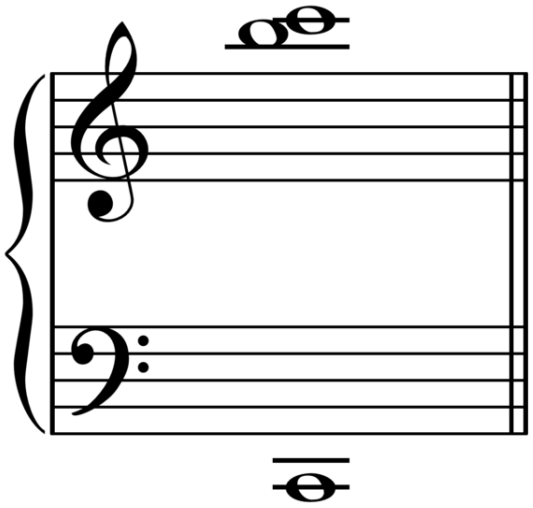
The **Pythagorean chromatic semitone** has a ratio of 2187/2048 (play). It is about 113.7 cents. It may also be called the **Pythagorean apotome**[10][11][12] or the *Pythagorean major semitone*. (*See Pythagorean interval.*)

$$\frac{2187}{2048} = \frac{3^7}{2^{11}} \approx 113.7\text{cents}$$

It can be thought of as the difference between four perfect octaves and seven just fifths, and functions as a chromatic semitone in a Pythagorean tuning.

The Pythagorean limma and Pythagorean apotome are enharmonic equivalents (chromatic semitones) and only a Pythagorean comma apart, in contrast to diatonic and chromatic semitones in meantone temperament and 5-limit just intonation.

7.4.5 Just intonation



16:15 diatonic semitone.

16:15 diatonic semitone Play .

'Larger' or major limma on C Play .

A minor second in just intonation typically corresponds to a pitch ratio of 16:15 (play) or 1.0666... (approximately 111.7 cents), called the **just diatonic semitone**.[13] This is a practical just semitone, since it is the difference between a perfect fourth and major third ($\frac{4}{3} \div \frac{5}{4} = \frac{16}{15}$).

The 16:15 just minor second arises in the C major scale between B & C and E & F, and is, "the sharpest dissonance found in the scale."[14]

An augmented unison in just intonation is another semitone of 25:24 (play) or 1.0416... (approximately 70.7 cents). It is the difference between a 5:4 major third and a 6:5 minor third. Composer Ben Johnston uses a sharp an accidental to indicate a note is raised 70.7 cents, or a flat to indicate a note is lowered 70.7 cents.[15]

Two other kinds of semitones are produced by 5-limit tuning. A chromatic scale defines 12 semitones as the 12 intervals between the 13 adjacent notes forming a full octave (e.g. from C4 to C5). The 12 semitones produced by a commonly used version of 5-limit tuning have four different sizes, and can be classified as follows:

- **Just, or smaller, or minor, chromatic semitone**, e.g. between E♭ and E:

$$S_1 = \frac{25}{24} \approx 70.7 \text{ cents}$$

- **Larger, or major, chromatic semitone**, or **larger limma**, or **major chroma**,[16] e.g. between D♭ and D:

$$S_2 = \frac{135}{128} \approx 92.2 \text{ cents}$$

- **Just, or smaller, or minor, diatonic semitone**, e.g. between C and D♭:

$$S_3 = \frac{16}{15} \approx 111.7 \text{ cents}$$

- **Larger, or major, diatonic semitone**, e.g. between A and B♭:

$$S_4 = \frac{27}{25} \approx 133.2 \text{ cents}$$

The most frequently occurring semitones are the just ones (S_3 and S_1): S_3 occurs six times out of 12, S_1 three times, S_2 twice, and S_4 only once.

The smaller chromatic and diatonic semitones differ from the larger by the syntonic comma (81:80 or 21.5 cents). The smaller and larger chromatic semitones differ from the respective diatonic semitones by the same 128:125 diesis as the above meantone semitones. Finally, while the inner semitones differ by the diaschisma (2048:2025 or 19.6 cents), the outer differ by the greater diesis (648:625 or 62.6 cents).

Other ratios may function as a minor second. In 7-limit there is the **septimal diatonic semitone** of 15:14 (play

) available between the 5-limit major seventh (15:8) and the 7-limit minor seventh (7:4). There is also a smaller **septimal chromatic semitone** of 21:20 (play) between a septimal minor seventh and a fifth (21:8) and an octave and a major third (5:2). Both are more rarely used than their 5-limit neighbours, although the former was often implemented by theorist Henry Cowell, while Harry Partch used the latter as part of his 43-tone scale.

Under 11-limit tuning, there is a fairly common *undecimal neutral second* (12:11) (play), but it lies on the boundary between the minor and major second (150.6 cents). In just intonation there are infinitely many possibilities for intervals that fall within the range of the semitone (e.g. the Pythagorean semitones mentioned above), but most of them are impractical.

In 17-limit just intonation, the major diatonic semitone is 15:14 or 119.4 cents (Play), and the minor diatonic semitone is 17:16 or 105.0 cents.[17]

Though the names *diatonic* and *chromatic* are often used for these intervals, their musical function is not the same as the two meantone semitones. For instance, 15:14 would usually be written as an augmented unison, functioning as the *chromatic* counterpart to a *diatonic* 16:15. These distinctions are highly dependent on the musical context, and just intonation is not particularly well suited to chromatic usage (diatonic semitone function is more prevalent).

7.4.6 Other equal temperaments

19-tone equal temperament distinguishes between the chromatic and diatonic semitones; in this tuning, the chromatic semitone is one step of the scale (play 63.2 cents), and the diatonic semitone is two (play 126.3 cents). 31-tone equal temperament also distinguishes between these two intervals, which become 2 and 3 steps of the scale, respectively. 53-ET has an even closer match to the two semitones with 3 and 5 steps of its scale while 72-ET uses 4 (play 66.7 cents) and 7 (play 116.7 cents) steps of its scale.

In general, because the two semitones can be viewed as the difference between major and minor thirds, and the difference between major thirds and perfect fourths, tuning systems that match these just intervals closely will also distinguish between the two types of semitones and match their just intervals closely.

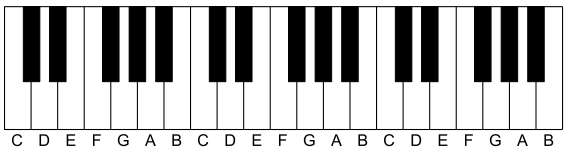
Chapter 8

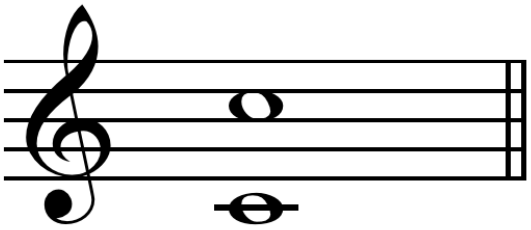
Octave

For other uses, see Octave (disambiguation).

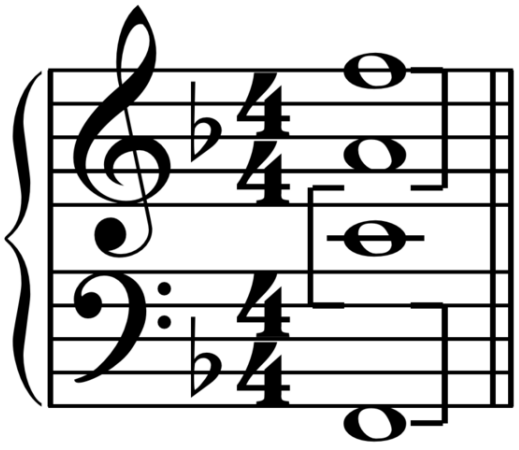
In music, an **octave** (Latin: *octavus*: eighth) or **perfect octave** is the interval between one musical pitch and another with half or double its frequency. It is defined by ANSI [1] as the unit of frequency level when the base of the logarithm is two. The octave relationship is a natural phenomenon that has been referred to as the "basic miracle of music", the use of which is "common in most musical systems".[2]



Layout of a musical keyboard (three octaves shown)



Perfect octave Play



Multi-octave F major chord with octaves marked by brackets. Play full chord , lowest octave , middle octave , or highest octave .

The most important musical scales are typically written using eight notes, and the interval between the first and last notes is an octave. For example, the C Major scale is typically written C D E F G A B C, the initial and final C's being an octave apart. Two notes separated by an octave have the same letter name and are of the same pitch class.

Three commonly cited examples of melodies featuring the perfect octave as their opening interval are "Singin' in the Rain", "Somewhere Over the Rainbow", and "Stranger on the Shore".

The interval between the first and second harmonics of the harmonic series is an octave.

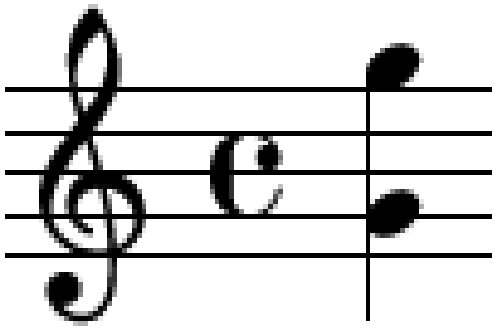
The octave has occasionally been referred to as a diapason.[3]

To emphasize that it is one of the perfect intervals (including unison, perfect fourth, and perfect fifth), the octave is designated **P8**. The octave above or below an indicated note is sometimes abbreviated **8va** (= Italian *all'ottava*), **8va bassa** (= Italian *all'ottava bassa*, sometimes also **8vb**), or simply **8** for the octave in the direction indicated by placing this mark above or below the staff.

8.1 Theory

For example, if one note has a frequency of 440 Hz, the note an octave above it is at 880 Hz, and the note an octave below is at 220 Hz. The ratio of frequencies of two notes an octave apart is therefore 2:1. Further octaves of a note occur at 2^n times the frequency of that note (where n is an integer), such as 2, 4, 8, 16, etc. and the reciprocal of that series. For example, 55 Hz and 440 Hz are one and two octaves away from 110 Hz because they are 0.5 (or 2^{-1}) and 4 (or 2^2) times the frequency, respectively.

After the unison, the octave is the simplest interval in music. The human ear tends to hear both notes as being essentially "the same", due to closely related harmonics.



An example of an octave, from G4 to G5

"Twinkle Twinkle Little Star" melody doubled in four octaves: consonant and equivalent. Play

Notes separated by an octave "ring" together, adding a pleasing sound to music. For this reason, notes an octave apart are given the same note name in the Western system of music notation—the name of a note an octave above A is also A. This is called **octave equivalency**, the assumption that pitches one or more octaves apart are musically equivalent in many ways, leading to the convention "that scales are uniquely defined by specifying the intervals within an octave".[4] The conceptualization of pitch as having two dimensions, pitch height (absolute frequency) and pitch class (relative position within the octave), inherently include octave circularity.[4] Thus all C♯s, or all 1s (if C = 0), in any octave are part of the same pitch class.

Octave equivalency is a part of most "advanced musical cultures", but is far from universal in "primitive" and early music.[5][6] The languages in which the oldest extant written documents on tuning are written, Sumerian and Akkadian, have no known word for "octave". However, it is believed that a set of cuneiform tablets that collectively describe the tuning of a nine-stringed instrument, believed to be a Babylonian lyre, describe tunings for seven of the strings, with indications to tune the remaining two strings an octave from two of the seven tuned strings.[7] Leon Crickmore recently proposed that "The octave may not have been thought of as a unit in its own right, but rather by analogy like the first day of a new seven-day week".[8]

Monkeys experience octave equivalency, and its biological basis apparently is an octave mapping of neurons in the auditory thalamus of the mammalian brain.[9] Studies have also shown the perception of octave equivalence in rats (Blackwell & Schlosberg, 1943), human infants

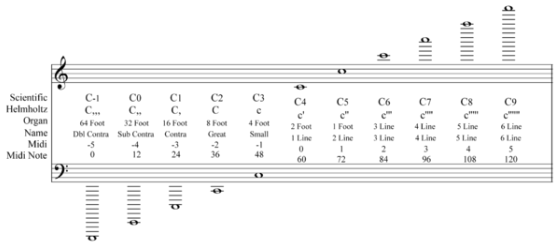
"Twinkle Twinkle Little Star" melody doubled at fifths: fairly consonant but not equivalent. Play

(Demany & Armand, 1984),[10] and musicians (Allen, 1967) but not starlings (Cynx, 1993), 4-9 year old children (Sergeant, 1983), or nonmusicians (Allen, 1967).[4]

"Twinkle Twinkle Little Star" melody doubled at seconds: neither consonant nor equivalent. Play

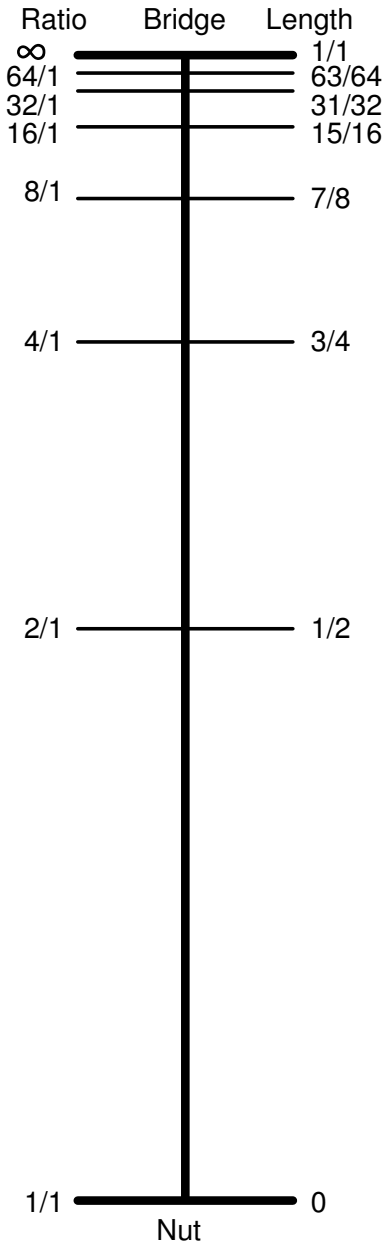
While octaves commonly refer to the **perfect octave** (P8), the interval of an octave in music theory encompasses chromatic alterations within the pitch class, meaning that G♮ to G♯ (13 semitones higher) is an Augmented octave (A8), and G♮ to G♭ (11 semitones higher) is a diminished octave (d8). The use of such intervals is rare, as there is frequently a preferable enharmonic notation available, but these categories of octaves must be acknowledged in any full understanding of the role and meaning of octaves more generally in music.

8.2 Notation



Octaves are identified with various naming systems. Among the most common are the Scientific, Helmholtz, Organ Pipe, Midi, and Midi Note systems.

An example of the same two notes expressed regularly, in an 8va bracket, and in a 15ma bracket



Six octaves on a monochord

In writing, a specific octave is often indicated through the addition of a number after the note letter name. Thus middle C is "C4", because of the note's position as the fourth C key on a standard 88-key piano keyboard, while the C above is "C5", in a system known as scientific pitch notation.

The notation **8va** is sometimes seen in sheet music, meaning "play this an octave higher than written" (***all' ottava***: "at the octave" or *all' 8va*). *8va* stands for *ottava*, the Italian word for octave (or "eighth"); the octave above may be specified as *ottava alta* or *ottava sopra*). Sometimes 8va is used to tell the musician to play a passage an octave *lower*, though the similar notation **8vb** (*ottava bassa* or *ottava sotta*) is more common. Similarly, **15ma** (*quindicesima*) means "play two octaves higher than written" and **15mb** (*quindicesima bassa*) means "play two octaves lower than written." The abbreviations **col 8**, **coll' 8**, and **c. 8va** stand for *coll'ottava*, meaning "play the notes in the passage together with the notes in the notated octaves". Any of these directions can be cancelled with the word *loco*, but often a dashed line or bracket indicates the extent of the music affected.[11]

For music-theoretical purposes (not on sheet music), *octave* can be abbreviated as **P8** (which is an abbreviation for Perfect Eighth, the interval between 12 semitones or an octave).

8.2.1 First octave

In music theory, the **first octave**, also called the **contra octave**, ranges from C1, or about 32.7 Hz, to C2, about 65.4 Hz, in equal temperament using A440 tuning. This is the lowest complete octave of most pianos (excepting the Bösendorfer Imperial Grand). The lowest notes of instruments such as double bass, electric bass, extended-range bass clarinet, contrabass clarinet, bassoon, contrabassoon, tuba and sousaphone are part of the first octave.

The ability of vocalists to sing competently in the first octave is rare, even for males. A singer who can reach notes in this range is known as a basso profondo, Italian for "deep bass". A Russian bass can also sing in this range, and the fundamental pitches sung by Tibetan monks and the throat singers of Siberia and Mongolia are in this range.

Chapter 9

Tritone

For other uses, see Tritone (disambiguation).

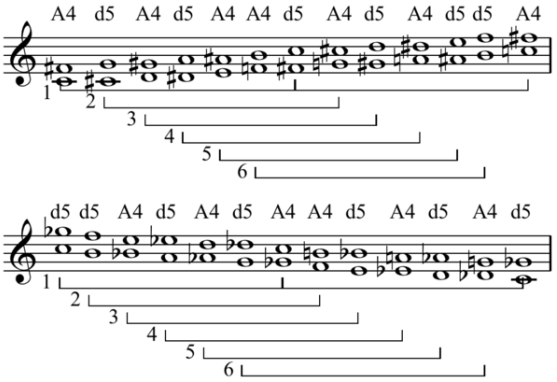
In music theory, the **tritone** is strictly defined as a musical interval composed of three adjacent whole tones.[1] For instance, the interval from F up to the B above it (in short, F–B) is a tritone as it can be decomposed into the three adjacent whole tones F–G, G–A, and A–B. According to this definition, within a diatonic scale there is only one tritone for each octave. For instance, the above-mentioned interval F–B is the only tritone which can be formed using the notes of the C major scale. A tritone is also commonly defined as an interval spanning six semitones. According to this definition, a diatonic scale contains two tritones for each octave. For instance, the above-mentioned C major scale contains the tritones F–B (from F to the B above it, also called **augmented fourth**) and B–F (from B to the F above it, also called **diminished fifth**, **semidiapente**, or **semitritonus**).[2]

In classical music, the tritone is a harmonic and melodic dissonance and is important in the study of musical harmony. The tritone can be used to avoid traditional tonality: "Any tendency for a tonality to emerge may be avoided by introducing a note three whole tones distant from the key note of that tonality."[3] Contrarily, the tritone found in the dominant seventh chord helps establish the tonality of a composition. These contrasting uses exhibit the flexibility, ubiquity, and distinctness of the tritone in music.

The condition of having tritones is called tritonia; that of having no tritones is atritonia. A musical scale or chord containing tritones is called tritonic; one without tritones is atritonic.

9.1 Augmented fourth and diminished fifth

Chromatic scale on C: full octave ascending and descending Play in equal temperament .



Full ascending and descending chromatic scale on C, with tritone above each pitch. Pairs of tritones that are inversions of each other are marked below.

The augmented fourth between C and F♯ and the diminished fifth between C and G♭ are enharmonically equivalent intervals. Both are 600 cents wide in 12-TET. Play .

Since a chromatic scale is formed by 12 pitches (each a semitone apart from its neighbors), it contains 12 distinct tritones, each starting from a different pitch and spanning six semitones. According to a complex but widely used naming convention, six of them are classified as *augmented fourths*, and the other six as *diminished fifths*.

Under that convention, a *fourth* is an interval encompassing four staff positions, while a *fifth* encompasses five staff positions (see interval number for more details). The augmented fourth (*A4*) and diminished fifth (*d5*) are defined as the intervals produced by widening the perfect fourth and narrowing the perfect fifth by one chromatic semitone.[4] They both span six semitones, and they are the inverse of each other, meaning that their sum is exactly equal to one perfect octave (A4 + d5 = P8). In 12-tone equal temperament, the most commonly used tuning system, the A4 is equivalent to a d5, as both have the size

of exactly half an octave. In most other tuning systems, they are not equivalent, and neither is exactly equal to half an octave.

Any augmented fourth can be decomposed into three whole tones. For instance, the interval F–B is an augmented fourth and can be decomposed into the three adjacent whole tones F–G, G–A, and A–B.

The above is not possible for the diminished fifth. The reason is that a whole tone is a major second, and according to a rule explained elsewhere, the composition of three seconds is always a fourth (for instance, an A4). To obtain a fifth (for instance, a d5), it is necessary to add another second. For instance, using the notes of the C major scale, the diminished fifth B–F can be decomposed into the four adjacent intervals

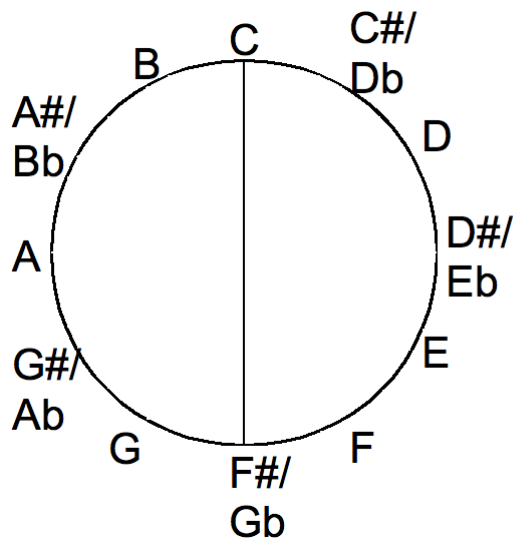
> B–C (minor second), C–D (major second), D–E (major second), and E–F (minor second).

Using the notes of a chromatic scale, B–F may be also decomposed into the four adjacent intervals

> B–C♯ (major second), C♯–D♯ (major second), D♯–E♯ (major second), and E♯–F (diminished second).

Notice that the latter diminished second is formed by two enharmonically equivalent notes (E♯ and F). On a piano keyboard, these notes are produced by the same key. However, in the above-mentioned naming convention, they are considered to be different notes, as they are written on different staff positions.

9.2 Definitions



Tritone drawn in the chromatic circle.

A tritone (abbreviation: *TT*) is traditionally defined as a musical interval composed of three whole tones. As the symbol for whole tone is *T*, this definition may be also written as follows:

$$TT = T+T+T$$

Only if the three tones are of the same size (which is not the case for many tuning systems) can this formula be simplified to:

$$TT = 3T$$

This definition, however, has two different interpretations (broad and strict).

9.2.1 Broad interpretation (chromatic scale)

In a chromatic scale, the interval between any note and the previous or next is a semitone. Using the notes of a chromatic scale, each tone can be divided into two semitones:

$$T = S+S$$

For instance, the tone from C to D (in short, C–D) can be decomposed into the two semitones C–C♯ and C♯–D by using the note C♯, which in a chromatic scale lies between C and D. This means that, when a chromatic scale is used, a tritone can be also defined as any musical interval spanning six semitones:

$$TT = T+T+T = S+S+S+S+S+S.$$

According to this definition, with the twelve notes of a chromatic scale it is possible to define twelve different tritones, each starting from a different note and ending six notes above it. Although all of them span six semitones, six of them are classified as A4, and the other six as d5.

9.2.2 Strict interpretation (diatonic scale)

Within a diatonic scale, whole tones are always formed by adjacent notes (such as C and D) and therefore they are regarded as incomposite intervals. In other words, they cannot be divided into smaller intervals. Consequently, in this context the above-mentioned "decomposition" of the tritone into six semitones is typically not allowed.

If a diatonic scale is used, with its 7 notes it is possible to form only one sequence of three adjacent whole tones (*T*+*T*+*T*). This interval is an A4. For instance, in the C major diatonic scale (C–D–E–F–G–A–B–...), the only

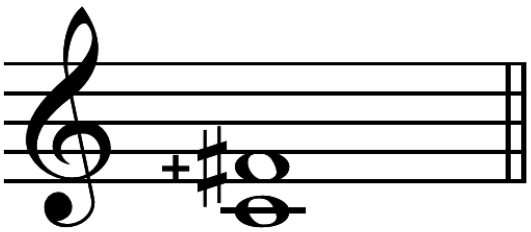
tritone is from F to B. It is a tritone because F–G, G–A, and A–B are three adjacent whole tones. It is a *fourth* because the notes from F to B are four (F, G, A, B). It is *augmented* (i.e., widened) because it is wider than most of the fourths found in the scale (they are perfect fourths).

According to this interpretation, the d5 is not a tritone. Indeed, in a diatonic scale, there's only one d5, and this interval does not meet the strict definition of tritone, as it is formed by one semitone, two whole tones, and another semitone:

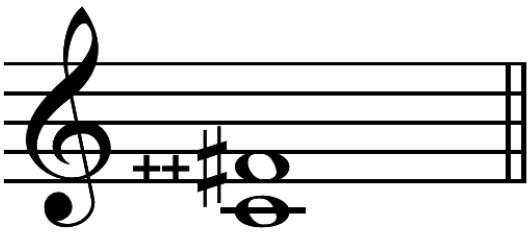
$$d5 = S+T+T+S.$$

For instance, in the C major diatonic scale, the only d5 is from B to F. It is a *fifth* because the notes from B to F are five (B, C, D, E, F). It is *diminished* (i.e. narrowed) because it is smaller than most of the fifths found in the scale (they are perfect fifths).

9.3 Size in different tuning systems



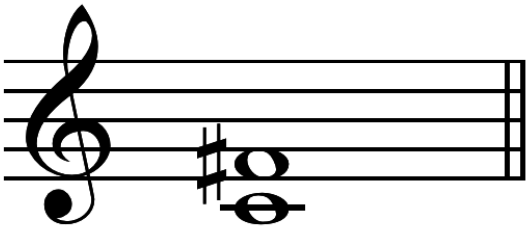
Tritone: just augmented fourth between C and F♯+ Play 45:32 (590.22 cents) .



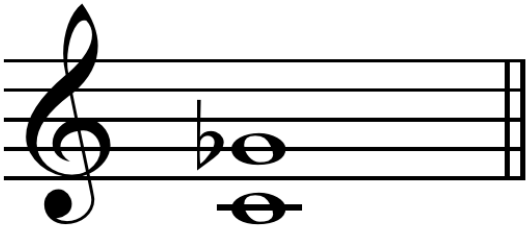
Tritone: Pythagorean augmented fourth between C and F♯++ Play 729:512 (611.73 cents) .

In 12-tone equal temperament, the A4 is exactly half an octave (i.e., a ratio of $\sqrt{2}$:1 or 600 cents; play). The inverse of 600 cents is 600 cents. Thus, in this tuning system, the A4 and its inverse (d5) are equivalent.

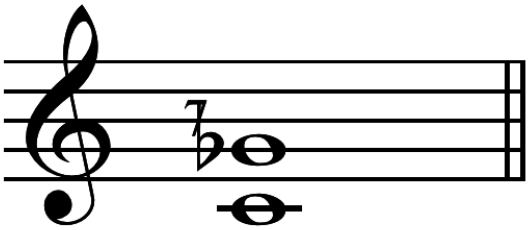
The half-octave or equal tempered A4 and d5 are unique in being equal to their own inverse (each to the other). In other meantone tuning systems, besides 12-tone equal temperament, A4 and d5 are distinct intervals because neither is exactly half an octave. In any meantone tuning near to $^{2}/_{9}$-comma meantone the A4 will be near to the



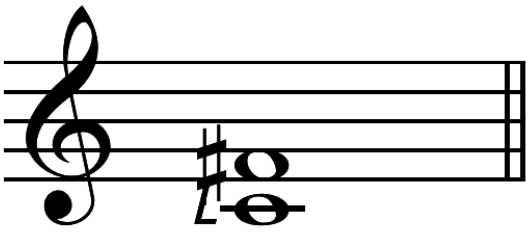
Tritone: the classic augmented fourth between C and F♯ Play 25:18 (568.72 cents)



Tritone: the classic diminished fifth between C and G♭ Play 36:25 (631.28 cents)



Lesser septimal tritone on between C and G♭[5] Play 7:5 (582.51 cents) .



Greater septimal tritone between C and F♯[5] Play 10:7 (617.49 cents) .

ratio $^{7}/_{5}$ (582.51) and the d5 to $^{10}/_{7}$ (617.49), which is what these intervals are taken to be in septimal meantone temperament. In 31 equal temperament, for example, the A4 is 619.35 cents, whereas the d5 is 580.65 cents. This is perceptually indistinguishable from septimal meantone temperament.

Since they are the inverse of each other, by definition A4 and d5 always add up to exactly one perfect octave:

$$A4 + d5 = P8.$$

On the other hand, two A4 add up to six whole tones. In equal temperament, this is equal to exactly one perfect octave:

$$A4 + A4 = P8.$$

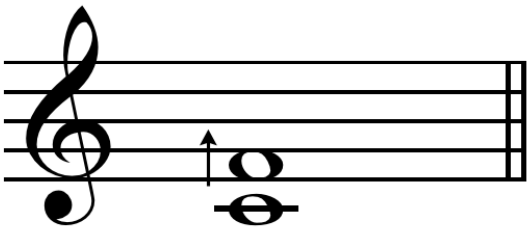
In quarter-comma meantone temperament, this is a diesis (128/125) less than a perfect octave:

$$A4 + A4 = P8 - diesis.$$

In just intonation several different sizes can be chosen both for the A4 and the d5. For instance, in 5-limit tuning, the A4 is either 45/32[6][7][8] or 25/18,[9] and the d5 is either 64/45 Play or 36/25,[10] or 1024:729 Play . The 64:45 just diminished fifth arises in the C major scale between B and F, consequently the 45:32 augmented fourth arises between F and B.[11]

These ratios are not in all contexts regarded as strictly just but they are the justest possible in 5-limit tuning. 7-limit tuning allows for the justest possible ratios (ratios with the smallest numerator and denominator), namely 7/5 for the A4 (about 582.5 cents, also known as septimal tritone) and 10/7 for the d5 (about 617.5 cents, also known as Euler's tritone).[6][12][13] These ratios are more consonant than 17/12 (about 603.0 cents) and 24/17 (about 597.0 cents), which can be obtained in 17-limit tuning, yet the latter are also fairly common, as they are closer to the equal-tempered value of 600.0 cents.

9.4 Eleventh harmonic



Eleventh harmonic between C and F↑. Play 11:8 (551.32 cents)

Known as the lesser undecimal tritone or undecimal semi-augmented fourth, 11:8 (551.318 cents), the ratio of the eleventh harmonic (F♯4 above C1), is found in some just tunings and on many instruments. For example, very long alphorns may reach the twelfth harmonic and transcriptions of their music usually show the eleventh harmonic sharp (F♯ above C, for example), as in Brahms's First Symphony.[14] This note is often corrected to 4:3 on the natural horn in just intonation or Pythagorean tunings, but the pure eleventh harmonic was used in pieces including Britten's *Serenade for tenor, horn and strings*.[15]

Use of the eleventh harmonic in the prologue to Britten's Serenade for tenor, horn and strings. *Play*

9.5 Dissonance and expressiveness

Compared to other commonly occurring intervals like the major second or the minor third, the augmented fourth and the diminished fifth (both two valid enharmonic interpretations of the tritone) are considered awkward intervals to sing. Western composers have traditionally avoided using it explicitly in their melody lines, often preferring to use passing notes (between the first and second note of the tritone) or skipping to a different note first (e.g., F→C→B or F→A→B instead of F→B) instead of using a direct leap of an augmented fourth or diminished fifth in their melodies. However, as time went by, composers have gradually used the tritone more and more in their music, disregarding its awkwardness and exploiting its expressiveness.

> The unstable character of the tritone sets it apart, as discussed in [28] [Paul Hindemith. *The Craft of Musical Composition*, Book I. Associated Music Publishers, New York, 1945]. It can be expressed as a ratio by compounding suitable superparticular ratios. Whether it is assigned the ratio 64/45 or 45/32, depending on the musical context, or indeed some other ratio, it is not superparticular, which is in keeping with its unique role in music.[16]

> Although this ratio [45/32] is composed of numbers which are multiples of 5 or under, they are excessively large for a 5-limit scale, and are sufficient justification, either in this form or as the tempered "tritone," for the epithet "diabolic," which has been used to characterize the interval. This is a case where, because of the largeness of the numbers, none but a temperament-perverted ear could possibly prefer 45/32 to a small-number interval of about the same width.[17]

> In the Pythagorean ratio 81/64 both numbers are multiples of 3 or under, yet because of their excessive largeness the ear certainly prefers 5/4 for this approximate degree, even though it involves a prime number higher than 3. In the case of the 45/32, 'tritone' our theorists have gone around their elbows to reach their thumbs, which could have been reached

simply and directly and non-'diabolically' via number 7.[17]

9.6 Common uses

9.6.1 Occurrences in diatonic scales

The augmented fourth (A4) occurs naturally between the fourth and seventh scale degrees of the major scale (for example, from F to B in the key of C major). It is also present in the natural minor scale as the interval formed between the second and sixth scale degrees (for example, from D to A♭ in the key of C minor). The melodic minor scale, having two forms, presents a tritone in different locations when ascending and descending (when the scale ascends, the tritone appears between the third and sixth scale degrees and the fourth and seventh scale degrees, and when the scale descends, the tritone appears between the second and sixth scale degrees). Supertonic chords using the notes from the natural minor mode will thus contain a tritone, regardless of inversion. Containing tritones, these scales are tritonic.

9.6.2 Occurrences in chords

The dominant seventh chord in root position contains a diminished fifth (tritone) within its pitch construction: it occurs between the third and seventh above the root. In addition, augmented sixth chords, some of which are enharmonic to dominant seventh chords, contain tritones spelled as augmented fourths (for example, the German sixth, from A to D♯ in the key of A minor); the French sixth chord can be viewed as a superposition of two tritones a major second apart.

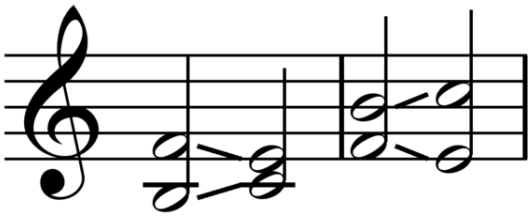
The diminished triad also contains a tritone in its construction, deriving its name from the diminished-fifth interval (i.e. a tritone). The half-diminished seventh chord contains the same tritone, while the fully diminished seventh chord is made up of two superposed tritones a minor third apart.

Other chords built on these, such as ninth chords, often include tritones (as diminished fifths).

9.6.3 Resolution

In all of the sonorities mentioned above, used in functional harmonic analysis, the tritone pushes towards resolution, generally resolving by step in contrary motion. This determines the resolution of chords containing tritones.

The augmented fourth resolves outward to a minor or major sixth. The inversion of this, a diminished fifth, resolves inward to a major or minor third. The diminished fifth is often called a tritone in modern tonal theory,



Tritone resolution inward (Play), and outwards (Play).

but functionally and notationally it can only resolve inwards as a diminished fifth and is therefore not reckoned a tritone—that is, an interval composed of three adjacent whole tones—in mid-renaissance (early 16th-century)[18] through baroque music theory.

9.6.4 Other uses

The tritone is also one of the defining features of the Locrian mode, being featured between the $\hat{1}$ and fifth scale degrees.

The half-octave tritone interval is used in the musical/auditory illusion known as the tritone paradox.

9.7 Historical uses

The theme opening Claude Debussy's Prélude à l'après-midi d'un faune *outlines a tritone (between C♯ and G) Play*

The tritone is a restless interval, classed as a dissonance in Western music from the early Middle Ages through to the end of the common practice period. This interval was frequently avoided in medieval ecclesiastical singing because of its dissonant quality. The first explicit prohibition of it seems to occur with the development of Guido of Arezzo's hexachordal system, which made B♭ a diatonic note, namely as the fourth degree of the hexachord on F. From then until the end of the Renaissance the tritone was regarded as an unstable interval and rejected as a consonance by most theorists.[19]

The name *diabolus in musica* ("the Devil in music") has been applied to the interval from at least the early 18th century, though its use is not restricted to the tritone. Andreas Werckmeister cites this term in 1702 as being used by "the old authorities" for both the tritone and for the clash between chromatically related tones such as F and F♯,[20] and five years later likewise calls "diabolus in

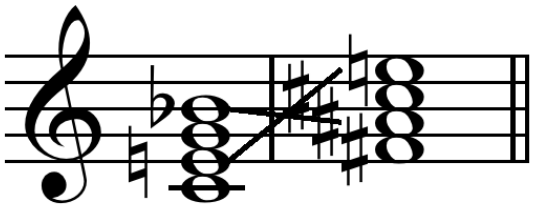
musica" the opposition of "square" and "round" B (B♮ and B♭, respectively) because these notes represent the juxtaposition of "mi contra fa".[21] Johann Joseph Fux cites the phrase in his seminal 1725 work *Gradus ad Parnassum*, Georg Philipp Telemann in 1733 describes, "mi against fa", which the ancients called "Satan in music", and Johann Mattheson in 1739 writes that the "older singers with solmization called this pleasant interval 'mi contra fa' or 'the devil in music'".[22] Although the latter two of these authors cite the association with the devil as from the past, there are no known citations of this term from the Middle Ages, as is commonly asserted.[23] However Denis Arnold, in the *New Oxford Companion to Music*, suggests that the nickname was already applied early in the medieval music itself:

> It seems first to have been designated as a "dangerous" interval when **Guido of Arezzo** developed his system of hexachords and with the introduction of B flat as a diatonic note, at much the same time acquiring its nickname of "Diabolus in Musica" ("the devil in music").[24]

Because of that original symbolic association with the devil and its avoidance, this interval came to be heard in Western cultural convention as suggesting an "evil" connotative meaning in music. Today the interval continues to suggest an "oppressive", "scary", or "evil" sound and is known colloquially as "The Devil's Interval". However, suggestions that singers were excommunicated or otherwise punished by the Church for invoking this interval are likely fanciful. At any rate, avoidance of the interval for musical reasons has a long history, stretching back to the parallel organum of the *Musica Enchiriadis*. In all these expressions, including the commonly cited *"mi contra fa est diabolus in musica"*, the "mi" and "fa" refer to notes from two adjacent hexachords. For instance, in the tritone B–F, B would be "mi", that is the third scale degree in the "hard" hexachord beginning on G, while F would be "fa", that is the fourth scale degree in the "natural" hexachord beginning on C.

Later in history with the rise of the Baroque and Classical music era, that interval came to be perfectly accepted, but yet was used in a specific controlled way, notably through the principle of the tension/release mechanism of the tonal system. In that system (which is the fundamental musical grammar of Baroque and Classical music), the tritone is one of the defining intervals of the dominant-seventh chord and two tritones separated by a minor third give the fully diminished seventh chord its characteristic sound. In minor, the diminished triad (comprising two minor thirds which together add up to a tritone) appears on the second scale degree, and thus features prominently in the progression ii^{o}-V-i. Often, the inversion ii^{o6} is used to move the tritone to the inner voices as this allows for stepwise motion in the bass to the dominant root. In three-part counterpoint, free use of the diminished triad in first inversion is permitted, as this eliminates the tritone relation to the bass.[25]

It is only with the Romantic music and modern classical music that composers started to use it totally freely, without functional limitations notably in an expressive way to exploit the "evil" connotations which are culturally associated to it (e.g., Franz Liszt's use of the tritone to suggest Hell in his *Dante Sonata*). The tritone was also exploited heavily in that period as an interval of modulation for its ability to evoke a strong reaction by moving quickly to distantly related keys. Later on, in twelve-tone music, serialism, and other 20th century compositional idioms it came to be considered as a neutral interval.[26] In some analyses of the works of 20th century composers, the tritone plays an important structural role; perhaps the most cited is the axis system, proposed by Ernő Lendvaï, in his analysis of the use of tonality in the music of Béla Bartók.[27] Tritone relations are also important in the music of George Crumb. George Harrison uses tritones on the downbeats of the opening phrases of the Beatles songs "The Inner Light", "Blue Jay Way" and "Within You Without You", creating a prolonged sense of suspended resolution.[28]



Tritone substitution: F♯7 may substitute for C7, and vice versa, because they both share E♮ and B♭/A♯ and due to voice leading considerations. Play

Tritones also became important in the development of jazz tertian harmony, where triads and seventh chords are often expanded to become 9th, 11th, or 13th chords, and the tritone often occurs as a substitute for the naturally occurring interval of the perfect 11th. Since the perfect 11th (i.e. an octave plus perfect fourth) is typically perceived as a dissonance requiring a resolution to a major or minor 10th, chords that expand to the 11th or beyond typically raise the 11th a semitone (thus giving us an augmented or sharp 11th, or an octave plus a tritone from the root of the chord) and present it in conjunction with the perfect 5th of the chord. Also in jazz harmony, the tritone is both part of the dominant chord and its substitute dominant (also known as the sub V chord). Because they share the same tritone, they are possible substitutes for one another. This is known as a tritone substitution. The tritone substitution is one of the most common chord and improvisation devices in jazz.

> In the theory of harmony it is known that a diminished interval needs to be resolved inwards, and an augmented interval outwards.

...and with the correct resolution of the *true* tritones this desire is totally satisfied. However, if one plays a *just* diminished fifth that is perfectly in tune, for example, there is no wish to resolve it to a major third. Just the opposite—aurally one wants to enlarge it to a minor sixth. The opposite holds true for the *just* augmented fourth....
These apparently contradictory aural experiences become understandable when the cents of both types of just tritones are compared with those of the true tritones and then read 'crossed-over'. One then notices that the just augmented fourth of 590.224 cents is only 2 cents bigger than the true diminished fifth of 588.270 cents, and that both intervals lie below the middle of the octave of 600.000 cents. It is no wonder that, following the ear, we want to resolve both downwards. The ear only desires the tritone to be resolved upwards when it is bigger than the middle of the octave. Therefore the opposite is the case with the just diminished fifth of 609.776 cents....[7]

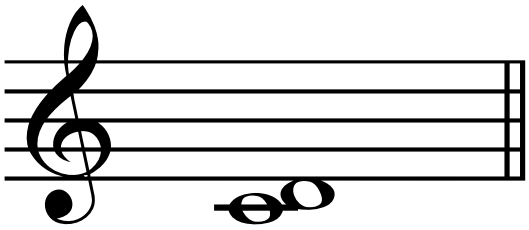
Chapter 10

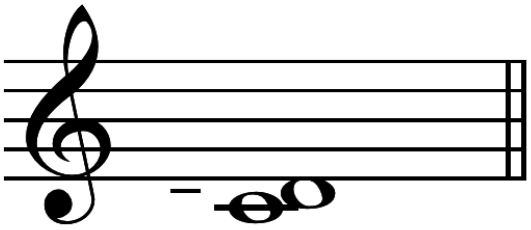
Major second

See also: Minor second and Diminished third

In Western music theory, a **major second** (sometimes also called **whole tone**) is a second spanning two semitones (Play). A second is a musical interval encompassing two adjacent staff positions (see Interval number for more details). For example, the interval from C to D is a major second, as the note D lies two semitones above C, and the two notes are notated on adjacent staff positions. Diminished, minor and augmented seconds are notated on adjacent staff positions as well, but consist of a different number of semitones (zero, one, and three).



Step: major second (major tone) Play .



Minor tone (10:9) Play .

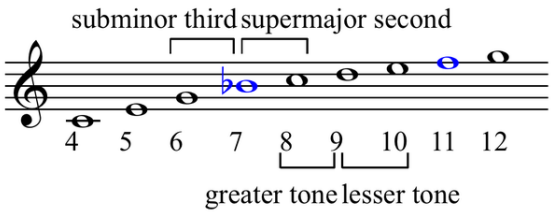
The major second is the interval that occurs between the first and second degrees of a major scale, the tonic and the supertonic. On a musical keyboard, a major second is the interval between two keys separated by one key, counting white and black keys alike. On a guitar string, it is the interval separated by two frets. In moveable-do solfège, it is the interval between *do* and *re*. It is considered a melodic step, as opposed to larger intervals called skips.

Intervals composed of two semitones, such as the major second and the diminished third, are also called **tones**, **whole tones**, or **whole steps**[1] In just intonation, major seconds can occur in at least two different frequency ratios:[2] 9:8 (about 203.9 cents) and 10:9 (about 182.4 cents). The largest (9:8) ones are called major tones or greater tones, the smallest (10:9) are called minor tones or lesser tones. Their size differs by exactly one syntonic comma (81:80, or about 21.5 cents). Some equal temperaments, such as 15-ET and 22-ET, also distinguish between a greater and a lesser tone.

The major second was historically considered one of the most dissonant intervals of the diatonic scale, although much 20th-century music saw it reimagined as a consonance. It is common in many different musical systems, including Arabic music, Turkish music and music of the Balkans, among others. It occurs in both diatonic and pentatonic scales.

Listen to a major second in equal temperament . Here, middle C is followed by D, which is a tone 200 cents sharper than C, and then by both tones together.

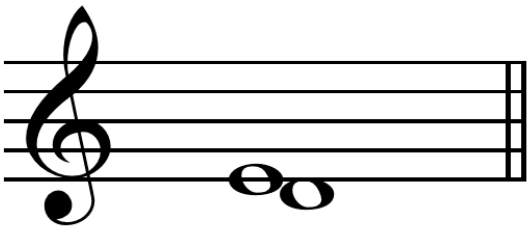
10.1 Major and minor tones



Origin of large and small seconds and thirds in harmonic series.[3]

In tuning systems using just intonation, such as 5-limit tuning, in which major seconds occur in two different sizes, the wider of them is called a **major tone** or **greater tone**, and the narrower a **minor tone** or, **lesser tone**. The difference in size between a major tone and a minor tone is equal to one syntonic comma (about 21.51 cents).

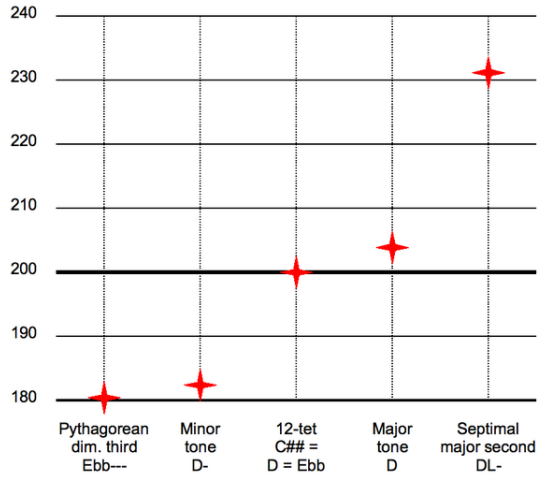
The major tone is the 9:8 interval[4] play , and it is an approximation thereof in other tuning systems, while the



Lesser tone on D. Play

minor tone is the 10:9 ratio[4] play . The major tone may be derived from the harmonic series as the interval between the eighth and ninth harmonics. The minor tone may be derived from the harmonic series as the interval between the ninth and tenth harmonics. The 10:9 minor tone arises in the C major scale between D and e and G and A, and is "a sharper dissonance" than 9:8.[5] The 9:8 major tone arises in the C major scale between C & D, F & G, and A & B.[5] This 9:8 interval was named epogdoon (meaning 'one eighth in addition') by the Pythagoreans.

Notice that in these tuning systems, a third kind of whole tone, even wider than the major tone, exists. This interval of two semitones, with ratio 256:225, is simply called the diminished third (for further details, see Five-limit tuning#Size of intervals).



Comparison, in cents, of intervals at or near a major second

Some equal temperaments also produce major seconds of two different sizes, called *greater* and *lesser tones* (or *major* and *minor tones*). For instance, this is true for 15-ET, 22-ET, 34-ET, 41-ET, 53-ET, and 72-ET. Conversely, in twelve-tone equal temperament, Pythagorean tuning, and meantone temperament (including 19-ET and 31-ET) all major seconds have the same size, so there cannot be a distinction between a greater and a lesser tone.

In any system where there is only one size of major second, the terms *greater* and *lesser tone* (or *major* and *minor tone*) are rarely used with a different meaning. Namely, they are used to indicate the two distinct kinds of whole tone, more commonly and more appropriately called *major second* (M2) and *diminished third* (d3). Similarly, major semitones and minor semitones are more often and more appropriately referred to as *minor seconds* (m2) and *augmented unisons* (A2), or *diatonic* and *chromatic semitones*.

Unlike almost all uses of the terms *major* and *minor*, these intervals span the *same* number of semitones. They both span 2 semitones, while, for example, a major third (4 semitones) and minor third (3 semitones) differ by one semitone. Thus, to avoid ambiguity, it is preferable to call them *greater tone* and *lesser tone* (see also greater and lesser diesis).

Two major tones equal a ditone.

10.2 *Epogdoon*

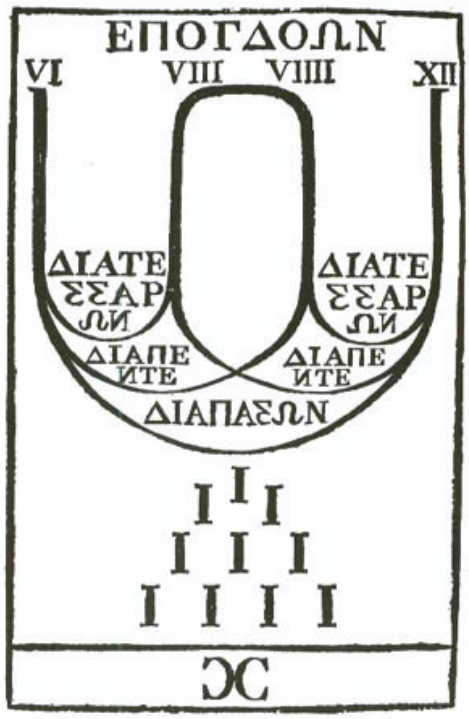


Figure 21. Diagram of tablet held up for Pythagoras. (From Bellori, *Descrizzione*. Photo: Clark Art Institute Library.)

Diagram showing relations between epogdoon, diatessaron, diapente, *and* diapason

In Pythagorean music theory, the ***epogdoon*** (Ancient Greek: ἐπόγδοον) is the interval with the ratio 9 to 8. The word is composed of the prefix *epi-* meaning "on top of" and *ogdoon* meaning "one eighth"; so it means "one eighth in addition". For example, the natural numbers are 8 and 9 in this relation (8+($\frac{1}{8}$ ×8)=9).

According to Plutarch, the Pythagoreans hated the number 17 because it separates the 16 from its Epogdoon 18.[6]

Detail of Raphael's School of Athens *showing* epogdoon *diagram*

"[*Epogdoos*] is the 9:8 ratio that corresponds to the tone, [*hêmiolios*] is the 3:2 ratio that is associated with the musical fifth, and [*epitritos*] is the 4:3 ratio associated with the musical fourth. It is common to translate ***epogdoos*** as 'tone' [major second]."[7]

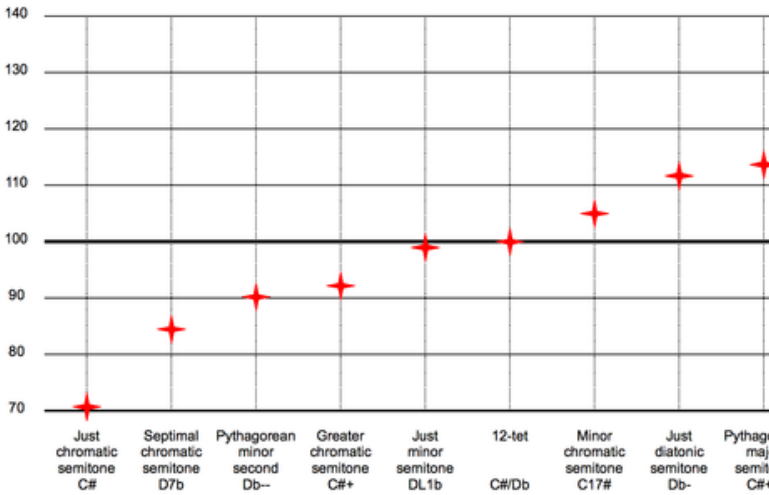
Chapter 11

Minor second

Not to be confused with minor tone.

In modern Western tonal music theory a **minor second**

Minor second on C. Play



is the interval between two notes on adjacent staff positions, or having adjacent note letters, whose alterations cause them to be one semitone or half-step apart, such as B and C or C and D♭.[1] The interval is also called a **diatonic semitone**.

Its inversion is a major seventh.

A helpful way to recognize a minor second is to hum the first two notes of Rosemary's Lullaby.

11.1 In other temperaments

In just intonation a 16:15 minor second arises in the C major scale between B & C and E & F, and is, "the sharpest dissonance found in the scale."[2] Play B & C

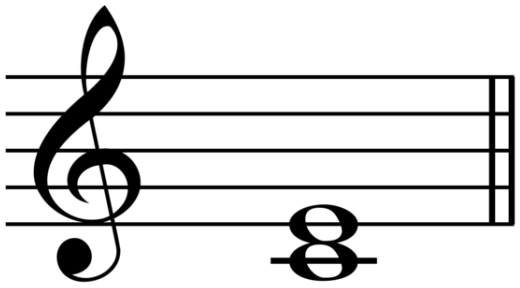
Chapter 12

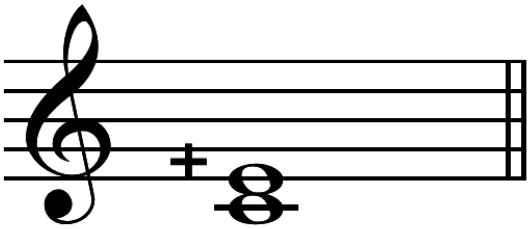
Major third

This article is about the musical interval. For the guitar tuning, see major thirds tuning.

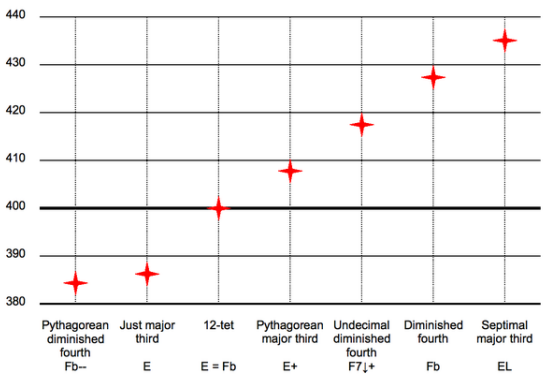
In classical music from Western culture, a **third** is a



Just major third.



Pythagorean major third.



Comparison, in cents, of intervals at or near a major third

musical interval encompassing three staff positions (see Interval number for more details), and the **major third** (🔊 Play) is a third spanning four semitones. Along with the minor third, the major third is one of two commonly occurring thirds. It is qualified as *major* because it is the larger of the two: the major third spans four semitones, the minor third three. For example, the interval from C to E is a major third, as the note E lies four semitones above C, and there are three staff positions from C to E. Diminished and augmented thirds span the same number of staff positions, but consist of a different number of semitones (two and five).

The major third may be derived from the harmonic series as the interval between the fourth and fifth harmonics. The major scale is so named because of the presence of this interval between its tonic and mediant (1st and 3rd) scale degrees. The major chord also takes its name from the presence of this interval built on the chord's root (provided that the interval of a perfect fifth from the root is also present or implied).

A major third in just intonation corresponds to a pitch ratio of 5:4 (🔊 play) (fifth harmonic in relation to the fourth) or 386.31 cents; in equal temperament, a major third is equal to four semitones, a ratio of $2^{1/3}$:1 (about 1.2599) or 400 cents, 13.69 cents wider than the 5:4 ratio. The older concept of a ditone (two 9:8 major seconds) made a dissonantly wide major third with the ratio 81:64 (🔊 play). The septimal major third is 9:7, the **undecimal major third** is 14:11, and the **tridecimal major third** is 13:10.

A helpful way to recognize a major third is to hum the first two notes of "Kumbaya" or of "When the Saints Go Marching In". A descending major third is heard at the starts of "Goodnight, Ladies" and "Swing Low, Sweet Chariot".

In equal temperament three major thirds in a row are equal to an octave (for example, A♭ to C, C to E, and E to G♯; G♯ and A♭ represent the same note). This is sometimes called the "circle of thirds". In just intonation, however, three 5:4 major thirds are less than an octave. For example, three 5:4 major thirds from C is B♯ (C to E to G♯ to B♯). The difference between this just-tuned B♯ and C, like that between G♯ and A♭, is called a diesis, about 41 cents.

The major third is classed as an imperfect consonance and is considered one of the most consonant intervals after the unison, octave, perfect fifth, and perfect fourth. In the common practice period, thirds were considered interesting and dynamic consonances along with their inverses the sixths, but in medieval times they were considered dissonances unusable in a stable final sonority.

A diminished fourth is enharmonically equivalent to a major third (that is, it spans the same number of semitones). For example, B–D♯ is a major third; but if the same pitches are spelled B and E♭, the interval is instead a diminished fourth. B–E♭ occurs in the C harmonic minor scale.

The major third is used in guitar tunings. For the standard tuning, only the interval between the 3rd and 2nd strings (G to B, respectively) is a major third; each of the intervals between the other pairs of consecutive strings is a perfect fourth. In an alternative tuning, the major-thirds tuning, each of the intervals are major thirds.

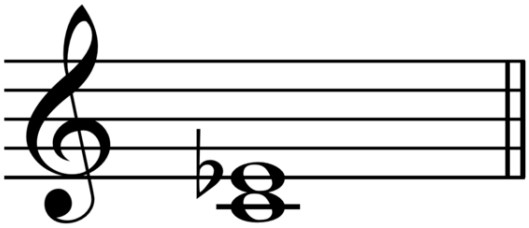
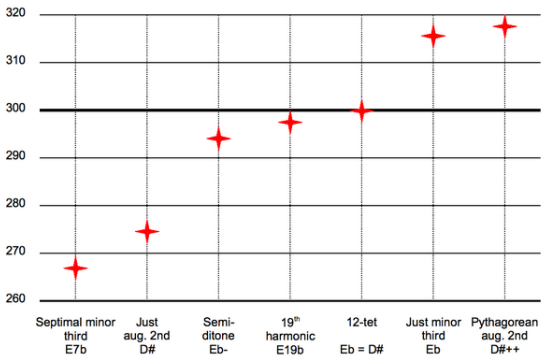
Chapter 13

Minor third



Minor third Play equal tempered or just (6:5).

19th harmonic (19:16), $E^{19}\flat$ Play .



Comparison, in cents, of intervals at or near a minor third

In the music theory of Western culture, a **minor third** is a musical interval that encompasses three half steps, or semitones. Staff notation represents the minor third as encompassing three staff positions (see: interval number). The minor third is one of two commonly occurring thirds. It is called *minor* because it is the smaller of the two: the major third spans an additional semitone. For example, the interval from A to C is a minor third, as the note C lies three semitones above A, and (coincidentally) there are three staff positions from A to C. Diminished and augmented thirds span the same number of staff positions, but consist of a different number of semitones (two and five). The minor third is a skip melodically.

A helpful way to recognize a minor third is to hum the first two notes of Greensleeves or Light My Fire.

The minor third may be derived from the harmonic series as the interval between the fifth and sixth harmonics, or from the 19th harmonic.

The minor third is commonly used to express sadness in music, and research shows that this mirrors its use in speech, as a tone similar to a minor third is produced during sad speech.[2] It is also a quartal (based on an ascendance of one or more perfect fourths) tertian interval, as opposed to the major third's quintality. The minor third is also obtainable in reference to a fundamental note from the undertone series, while the major third is obtainable as such from the overtone series. (See Otonality and Utonality.)

The minor scale is so named because of the presence of this interval between its tonic and mediant (1st and 3rd) scale degrees. Minor chords too take their name from the presence of this interval built on the chord's root (provided that the interval of a perfect fifth from the root is also present or implied).

A minor third, in just intonation, corresponds to a pitch ratio of 6:5 (play) or 315.64 cents. In an equal tempered tuning, a minor third is equal to three semitones, a ratio of $2^{1/4}$:1 (about 1.189), or 300 cents, 15.64 cents narrower than the 6:5 ratio. In other meantone tunings it is wider, and in 19 equal temperament it is very nearly the 6:5 ratio of just intonation; in more complex schismatic temperaments, such as 53 equal temperament, the "minor third" is often significantly flat (being close to Pythagorean tuning (play)), although the "augmented second" produced by such scales is often within ten cents of a pure 6:5 ratio. If a minor third is tuned in accordance with the fundamental of the overtone series, the result is a ratio of 19:16, this produces an interval of 297.51 cents. The 12-TET minor third (300 cents) more closely approximates the 19-limit (Limit (music)) minor third 16:19 Play (297.51 cents, the **nineteenth har-**

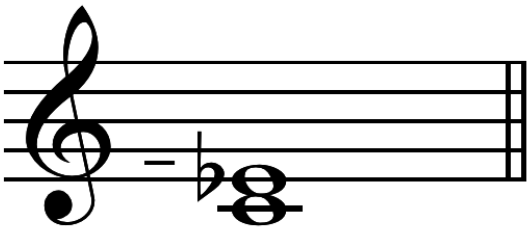
monic) with only 2.49 cents error.[3]

Other pitch ratios are given related names, the septimal minor third with ratio 7:6 and the tridecimal minor third with ratio 13:11 in particular.

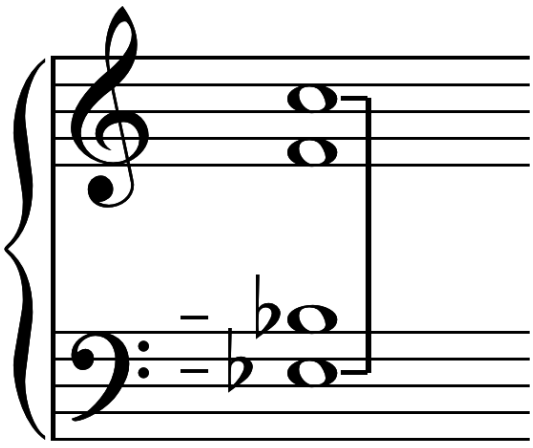
The minor third is classed as an imperfect consonance and is considered one of the most consonant intervals after the unison, octave, perfect fifth, and perfect fourth.

Instruments in A are a minor 3rd lower than the written pitch in the concert pitch (C), i.e. how they are heard. Therefore, to get the written pitch, transpose the concert pitch up a minor 3rd.

13.1 Pythagorean minor third



Semiditone (32:27) on C Play .



Semiditone as two octaves minus three justly tuned fifths.

In music theory, a **semiditone** (or **Pythagorean minor third**[4]) is the interval 32:27 (approximately 294.13 cents). It is the minor third in Pythagorean tuning. The 32:27 Pythagorean minor third arises in the C major scale between D and F.[5] Play

It can be thought of as two octaves minus three justly tuned fifths. It is narrower than a justly tuned minor third by a syntonic comma.

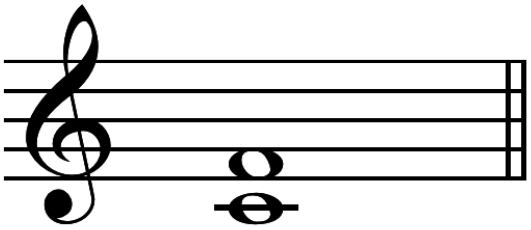
Chapter 14

Perfect fourth



Perfect fourth Play

In classical music from Western culture, a **fourth** is a musical interval encompassing four staff positions (see Interval number for more details), and the **perfect fourth** (Play) is a fourth spanning five semitones (half steps, or half tones). For example, the ascending interval from C to the next F is a perfect fourth, as the note F lies five semitones above C, and there are four staff positions from C to F. Diminished and augmented fourths span the same number of staff positions, but consist of a different number of semitones (four and six).

The perfect fourth may be derived from the harmonic series as the interval between the third and fourth harmonics. The term *perfect* identifies this interval as belonging to the group of perfect intervals, so called because they are neither major nor minor (unlike thirds, which are either minor or major) but perfect.

Up until the late 19th century, the perfect fourth was often called by its Greek name, ***diatessaron***.[1] Its most common occurrence is between the fifth and upper root of all major and minor triads and their extensions.

A perfect fourth in just intonation corresponds to a pitch ratio of 4:3, or about 498 cents (Play), while in equal temperament a perfect fourth is equal to five semitones, or 500 cents.

A helpful way to recognize a perfect fourth is to hum the starting of "El Cóndor Pasa", the “Bridal Chorus” from Wagner's *Lohengrin* ("*Treulich geführt*", the colloquially-titled "Here Comes the Bride"). Other examples are the first two notes of the Christmas carol "Hark! The Herald Angels Sing", and, for a descending perfect fourth, the second and third notes of "O Come All Ye Faithful".

The perfect fourth is a perfect interval like the unison, octave, and perfect fifth, and it is a sensory consonance. In common practice harmony, however, it is considered a stylistic dissonance in certain contexts, namely in two-voice textures and whenever it appears above the bass.[2] If the bass note also happens to be the chord’s root, the interval’s upper note almost always temporarily displaces the third of any chord, and, in the terminology used in popular music, is then called a *suspended fourth*.

Conventionally, adjacent strings of the double bass and of the bass guitar are a perfect fourth apart when unstopped, as are all pairs but one of adjacent guitar strings under standard guitar tuning. Sets of tom-tom drums are also commonly tuned in perfect fourths. The 4:3 just perfect fourth arises in the C major scale between G and C.[3] Play

14.1 History

The use of perfect fourths and fifths to sound in parallel with and to “thicken” the melodic line was prevalent in music prior to the European polyphonic music of the Middle Ages.

In the 13th century, the fourth and fifth together were the *concordantiae mediae* (middle consonances) after the unison and octave, and before the thirds and sixths. In the 15th century the fourth came to be regarded as dissonant on its own, and was first classed as a dissonance by Johannes Tinctoris in his *Terminorum musicae diffinitorium* (1473). In practice, however, it continued to be used as a consonance when supported by the interval of a third or fifth in a lower voice.[4]

Modern acoustic theory supports the medieval interpretation insofar as the intervals of unison, octave, fifth and fourth have particularly simple frequency ratios. The octave has the ratio of 2:1, for example the interval between a' at A440 and a'' at 880 Hz, giving the ratio 880:440, or 2:1. The fifth has a ratio of 3:2, and its complement has the ratio of 3:4. Ancient and medieval music theorists appear to have been familiar with these ratios, see for example their experiments on the Monochord.

In the years that followed, the frequency ratios of these intervals on keyboards and other fixed-tuning instruments

(Listen) with perfect (a), augmented (b) and diminished (c) fourths

would change slightly as different systems of tuning, such as meantone temperament, well temperament, and equal temperament were developed.

In early western polyphony, these simpler intervals (unison, octave, fifth and fourth) were generally preferred. However, in its development between the 12th and 16th centuries:

1. In the earliest stages, these simple intervals occur so frequently that they appear to be the favourite sound of composers.

2. Later, the more "complex" intervals (thirds, sixths, and tritones) move gradually from the margins to the centre of musical interest.

3. By the end of the Middle Ages, new rules for voice leading had been laid, re-evaluating the importance of unison, octave, fifth and fourth and handling them in a more restricted fashion (for instance, the later forbidding of parallel octaves and fifths).

The music of the 20th century for the most part discards the rules of "classical" western tonality. For instance, composers such as Erik Satie borrowed stylistic elements from the Middle Ages, but some composers found more innovative uses for these intervals.

14.1.1 Middle ages

In medieval music, the tonality of the common practice period had not yet developed, and many examples may be found with harmonic structures that are built on fourths and fifths. The Musica enchiriadis of the mid 10th century, a guidebook for musical practice of the time, described singing in parallel fourths, fifths, and octaves. This development continued, and the music of the Notre Dame school may be considered the apex of a coherent harmony in this style.

Fourths in Guillaume Du Fay's Antiphon Ave Maris Stella

For instance, in one Alleluia (Listen) by Pérotin, the fourth is favoured. Elsewhere, in parallel organum at the fourth, the upper line would be accompanied a fourth below. Also important was the practice of Fauxbourdon, which is a three voice technique (not infrequently improvisatory) in which the two lower voices proceed parallel to the upper voice at a fourth and sixth below. Fauxbourdon, while making extensive use of fourths, is also an important step towards the later triadic harmony of tonality, as it may be seen as a first inversion (or 6/3) triad.

This parallel 6/3 triad was incorporated into the contrapuntal style at the time, in which parallel fourths were sometimes considered problematic, and written around with ornaments or other modifications to the Fauxbourdon style. An example of this is the start of the Marian-Antiphon *Ave Maris Stella* (Listen) by Guillaume Dufay, a master of Fauxbourdon.

14.1.2 Renaissance and Baroque

The development of tonality continued through the Renaissance until it was fully realized at last by composers of the Baroque era.

Conventional closing cadences

As time progressed through the late Renaissance and early Baroque, the fourth became more understood as an interval that needed resolution. Increasingly the harmonies of fifths and fourths yielded to uses of thirds and sixths. In the example, cadence forms from works by Orlando di Lasso and Palestrina show the fourth being resolved as a suspension. (Listen)

In the early Baroque music of Claudio Monteverdi and Girolamo Frescobaldi triadic harmony was thoroughly utilized. Diatonic and chromatic passages strongly outlining the interval of a fourth appear in the *Lamento* genre, and often in *Passus duriusculus* passages of chromatic descent. In the madrigals of Claudio Monteverdi and Carlo Gesualdo the intensive interpretation of the text (Word painting) frequently highlights the shape of a fourth as an extremely delayed resolution of a fourth suspension. Also, in Frescobaldi's *Chromatic Toccata* of 1635 the outlined fourths overlap, bisecting various church modes.

In the first third of the 18th century, ground-laying theoretical treatises on composition and harmony were

written. Jean-Philippe Rameau completed his treatise *Le Traité de l'harmonie réduite à ses principes naturels* (French: the theory of harmony reduced to its natural principles) in 1722 which supplemented his work of four years earlier, *Nouveau Système de musique theoretique* (French: new system of music theory); these together may be considered the cornerstone of modern Music theory relating to consonance and harmony. The Austrian composer Johann Fux published in 1725 his powerful treatise on the composition of Counterpoint in the style of Palestrina under the title *Gradus ad Parnassum* (Latin: The Steps to Parnassus). He outlined various types of counterpoint (e.g., *note against note*), and suggested a careful application of the fourth so as to avoid dissonance.

14.1.3 Classical and Romantic

The blossoming of tonality and the establishment of well temperament in Bach's time both had a continuing influence up to the late Romantic period, and the tendencies towards quartal harmony were somewhat suppressed. An increasingly refined cadence, and triadic harmony defined the musical work of this era. Counterpoint was simplified to favour an upper line with a clear accompanying harmony. Still, there are many examples of dense counterpoint utilizing fourths in this style, commonly as part of the background urging the harmonic expression in a passage along to a climax. Mozart in his so-called *Dissonance Quartet* KV 465 (Listen) used Chromatic and Whole tone scales to outline fourths, and the subject of the fugue in the third movement of Beethoven's Piano sonata op. 110 (Listen) opens with three ascending fourths. These are all melodic examples, however, and the underlying harmony is built on thirds.

Composers started to reassess the quality of the fourth as a consonance rather than a dissonance. This would later influence the development of quartal and quintal harmony.

The "Tristan chord" in context

The *Tristan chord* is made up of the notes F♮, B♮, D♯ and G♯ and is the very first chord heard in Richard Wagner's opera *Tristan und Isolde*. The chord had been found in earlier works (notably Beethoven's Piano Sonata No. 18) but Wagner's usage was significant, first because it is seen as moving away from traditional tonal harmony and even towards atonality, and second because with this chord Wagner actually provoked the *sound* or structure of musical harmony to become more predominant than its *function*, a notion which was soon after to be explored by Debussy and others.

Measures 24 to 27 from Mussorgsky's The Hut on Fowl's Legs

Fourth-based harmony became important in the work of Slavic and Scandinavian composers such as Modest Mussorgsky, Leoš Janáček, and Jean Sibelius. These composers used this harmony in a pungent, uncovered, almost archaic way, often incorporating the Folk music of their particular homelands. Sibelius' *Piano Sonata* in F-Major op. 12 of 1893 used tremolo passages of near-quartal harmony in a way that was relatively hard and modern. Even in the example on the right from Mussorgsky's piano-cycle Pictures at an Exhibition *(Избушка на курьих ножках (Баба-Яга) - The Hut on Fowl's Legs)* (Listen) the fourth always makes an "unvarnished" entrance.

The Romantic composers Frédéric Chopin and Franz Liszt, had use the special "thinned out" sound of fourth-chord in late works for piano (*Nuages gris* (Fr: Grey Clouds), *La lugubre gondola* (Fr: The Mournful Gondola), and other works).

In the 1897 work *The Sorcerer's Apprentice (L'Apprenti sorcier)* by Paul Dukas, the repetition of rising fourths is a musical representation of the tireless work of out-of-control walking brooms causes the water level in the house to "rise and rise". Quartal harmony in Ravel's *Sonatine* and *Ma Mère l'Oye* (Fr: Mother Goose) would follow a few years later.

14.1.4 20th century music

Western classical music

Main article: quartal and quintal harmony

In the 20th century, harmony explicitly built on fourths and fifths became important. This became known as quartal harmony for chords based on fourths and quintal harmony for chords based on fifths. In the music of composers of early 20th century France, fourth chords became consolidated with Ninth chords, the Whole tone scale, the Pentatonic scale, and polytonality as part of their language, and quartal harmony became an important means of expression in music by Debussy, Maurice Ravel, and others. Examples are found in Debussy's orchestral work *La Mer* (The Sea) and in his piano works, in particular *La cathédrale engloutie* (The Sunken Cathedral) from his *Préludes* for piano, *Pour les quartes* (For Fourths) and *Pour les arpéges composées* (For Composite

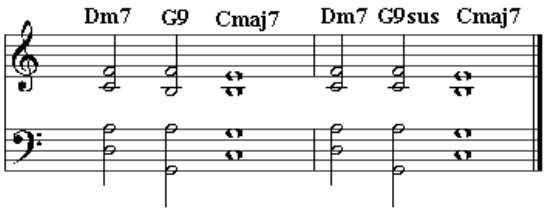
Quartal harmony in "Laideronnette" from Ravel's Ma Mère l'Oye. The top line uses the pentatonic scale.[5] *Play*

Arpeggios) from his *Etudes*.

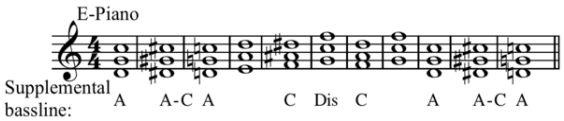
Jazz

Jazz uses quartal harmonies (usually called *voicing in fourths*).

Cadences are often "altered" to include unresolved *suspended chords* which include a fourth above the bass:



(Listen) The II-V-I Cadence (Listen) The Fourth-suspension or "Sus"-Chord



Fourths in Herbie Hancock's Maiden Voyage.

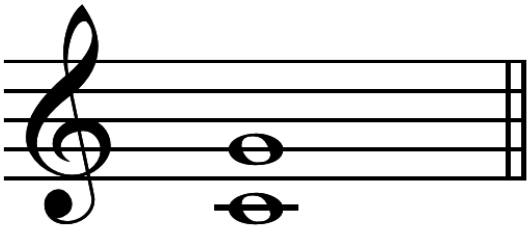
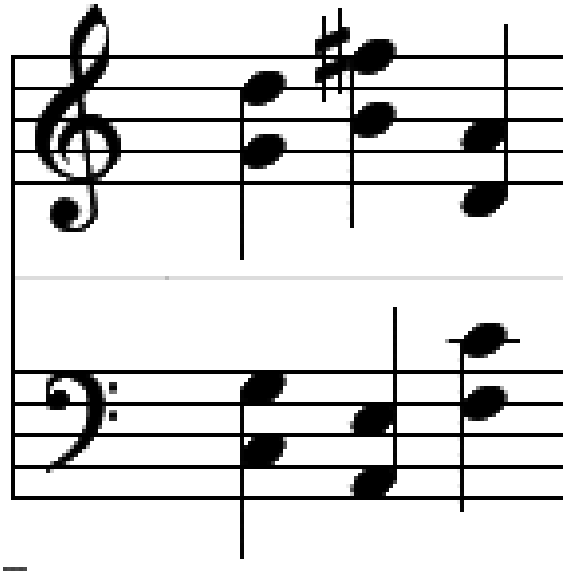
Chapter 15

Perfect fifth



Perfect fifth Play equal tempered and Play just.



Examples of perfect fifth intervals

In music theory, a **perfect fifth** is the musical interval corresponding to a pair of pitches with a frequency ratio of 3:2, or very nearly so.

In classical music from Western culture, a **fifth** is the interval from the first to the last of five consecutive notes in a diatonic scale. The perfect fifth (often abbreviated **P5**) spans seven semitones, while the diminished fifth spans six and the augmented fifth spans eight semitones. For example, the interval from C to G is a perfect fifth, as the note G lies seven semitones above C.[1] Play

The perfect fifth may be derived from the harmonic series as the interval between the second and third harmonics. In a diatonic scale, the dominant note is a perfect fifth above the tonic note.

The perfect fifth is more consonant, or stable, than any other interval except the unison and the octave. It occurs above the root of all major and minor chords (triads) and their extensions. Until the late 19th century, it was often referred to by one of its Greek names, ***diapente***.[2] Its inversion is the perfect fourth. The octave of the fifth is the twelfth.

A helpful way to recognize a perfect fifth is to hum the starting of *Twinkle, Twinkle, Little Star*; the pitch of the first "twinkle" is the root note and pitch of the second "twinkle" is a perfect fifth above it.

15.1 Alternative definitions

The term *perfect* identifies the perfect fifth as belonging to the group of *perfect intervals* (including the unison, perfect fourth and octave), so called because of their simple pitch relationships and their high degree of consonance.[3] When an instrument with only twelve notes to an octave (such as the piano) is tuned using Pythagorean tuning, one of the twelve fifths (the wolf fifth) sounds severely dissonant and can hardly be qualified as "perfect", if this term is interpreted as "highly consonant". However, when using correct enharmonic spelling, the wolf fifth in Pythagorean tuning or meantone temperament is actually not a perfect fifth but a diminished sixth (for instance G♯–E♭).

Perfect intervals are also defined as those natural intervals whose inversions are also perfect, where natural, as opposed to altered, designates those intervals between a base note and another note in the major diatonic scale starting at that base note (for example, the intervals from C to C, D, E, F, G, A, B, C, with no sharps or flats); this definition leads to the perfect intervals being only the unison, fourth, fifth, and octave, without appealing to degrees of consonance.[4]

The term *perfect* has also been used as a synonym of *just*, to distinguish intervals tuned to ratios of small integers from those that are "tempered" or "imperfect" in various other tuning systems, such as equal temperament.[5][6]

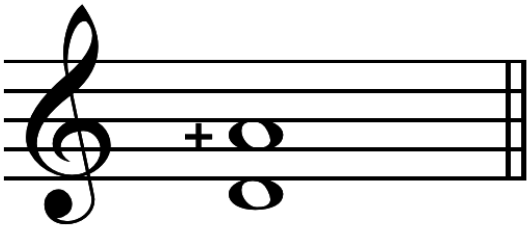
The perfect unison has a pitch ratio 1:1, the perfect octave 2:1, the perfect fourth 4:3, and the perfect fifth 3:2.

Within this definition, other intervals may also be called perfect, for example a perfect third (5:4)[7] or a perfect major sixth (5:3).[8]

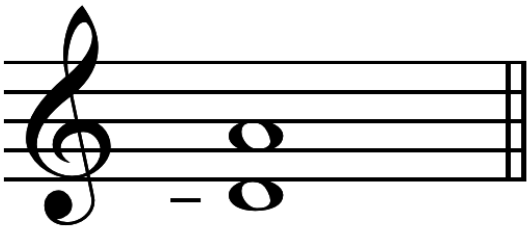
15.2 Other qualities of fifth

In addition to perfect, there are two other kinds, or qualities, of fifths: the diminished fifth, which is one chromatic semitone smaller, and the augmented fifth, which is one chromatic semitone larger. In terms of semitones, these are equivalent to the tritone (or augmented fourth), and the minor sixth, respectively.

15.3 Pitch ratio



Just perfect fifth on D Play . The perfect fifth above D (A+, 27/16) is a syntonic comma (81/80 or 21.5 cents) higher than the just major sixth above middle C: (A♯, 5/3).[9]



Just perfect fifth below A Play . The perfect fifth below A (D-, 10/9) is a syntonic comma lower than the just/Pythagorean major second above middle C: (D♯, 9/8).[9]

The justly tuned pitch ratio of a perfect fifth is 3:2 (also known, in early music theory, as a *hemiola*[10][11]), meaning that the upper note makes three vibrations in the same amount of time that the lower note makes two. The just perfect fifth can be heard when a violin is tuned: if adjacent strings are adjusted to the exact ratio of 3:2, the result is a smooth and consonant sound, and the violin sounds in tune.

Keyboard instruments such as the piano normally use an equal tempered version of the perfect fifth, enabling the instrument to play in all keys. In 12-tone equal temperament, the frequencies of the tempered perfect fifth are in the ratio $(\sqrt[12]{2})^7$ or approximately 1.498307. An equally tempered perfect fifth, defined as 700 cents, is about two cents narrower than a just perfect fifth, which is approximately 701.955 cents.

Kepler explored musical tuning in terms of integer ratios, and defined a "lower imperfect fifth" as a 40:27 pitch ratio, and a "greater imperfect fifth" as a 243:160 pitch ratio.[12] His lower perfect fifth ratio of 1.4815 (680 cents) is much more "imperfect" than the equal temperament tuning (700 cents) of 1.498 (relative to the ideal 1.50). Helmholtz uses the ratio 301:200 (708 cents) as an example of an imperfect fifth; he contrasts the ratio of a fifth in equal temperament (700 cents) with a "perfect fifth" (3:2), and discusses the audibility of the beats that result from such an "imperfect" tuning.[13]

15.4 Use in harmony

Moritz Hauptmann describes the octave as a higher unity appearing as such within the triad, produced from the prime unity of first the octave, then fifth, then third, "which is the union of the former."[14] Hermann von Helmholtz argues that some intervals, namely the perfect fourth, fifth, and octave, "are found in all the musical scales known", though the editor of the English translation of his book notes the fourth and fifth may be interchangeable or indeterminate.[15]

The perfect fifth is a basic element in the construction of major and minor triads, and their extensions. Because these chords occur frequently in much music, the perfect fifth occurs just as often. However, since many instruments contain a perfect fifth as an overtone, it is not unusual to omit the fifth of a chord (especially in root position).

The perfect fifth is also present in seventh chords as well as "tall tertian" harmonies (harmonies consisting of more than four tones stacked in thirds above the root). The presence of a perfect fifth can in fact soften the dissonant intervals of these chords, as in the major seventh chord in which the dissonance of a major seventh is softened by the presence of two perfect fifths.

One can also build chords by stacking fifths, yielding quintal harmonies. Such harmonies are present in more modern music, such as the music of Paul Hindemith. This harmony also appears in Stravinsky's *The Rite of Spring* in the *Dance of the Adolescents* where four C Trumpets, a Piccolo Trumpet, and one Horn play a five-tone B-flat quintal chord.[16]

15.5 Bare fifth, open fifth, or empty fifth

A **bare fifth**, **open fifth** or **empty fifth** is a chord containing only a perfect fifth with no third. The closing chord of the Kyrie in Mozart's Requiem and of the first movement of Bruckner's Ninth Symphony are both examples of pieces ending on an empty fifth. These "chords" are common in Sacred Harp singing and throughout rock music. In hard rock, metal, and punk music, overdriven or distorted guitar can make thirds sound muddy while the **bare fifth** remains crisp. In addition, fast chord-based passages are made easier to play by combining the four most common guitar hand shapes into one. Rock musicians refer to them as *power chords* and often include octave doubling (i.e., their bass note is doubled one octave higher, e.g. F3-C4-F4).

An **empty fifth** is sometimes used in traditional music, e.g., in Asian music and in some Andean music genres of pre-Columbian origin, such as k'antu and sikuri. The same melody is being led by parallel fifths and octaves during all the piece. Hear examples: Play K'antu , Play Pacha Siku .

Western composers may use the interval to give a passage an exotic flavor.[17]

15.6 Use in tuning and tonal systems

The just perfect fifth, together with the octave, forms the basis of Pythagorean tuning. A flattened perfect fifth is likewise the basis for meantone tuning.

The circle of fifths is a model of pitch space for the chromatic scale (chromatic circle), which considers nearness as the number of perfect fifths required to get from one note to another, rather than chromatic adjacency.

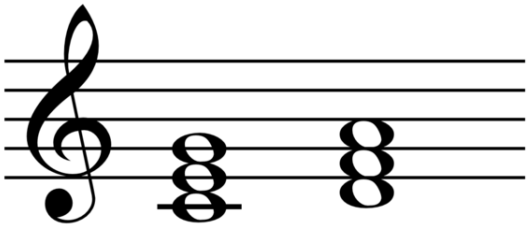
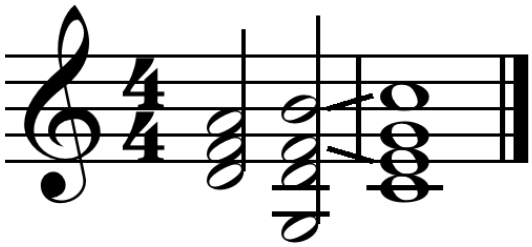
Chapter 16

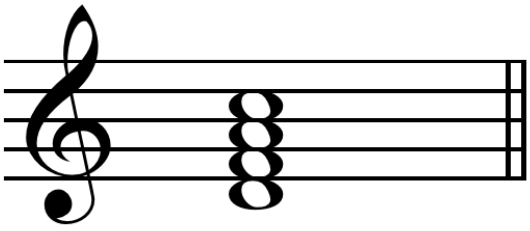
Supertonic



Tonic and supertonic in C Play . C major and D minor chords.

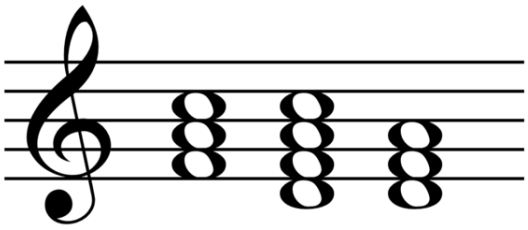


Supertonic (ii) in ii-V-I progression on C, found at the end of the circle progression Play

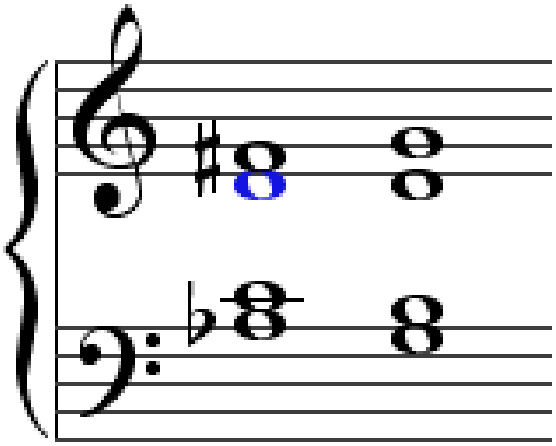


*Minor seventh chord on d, ii^{7} or **supertonic seventh chord** in C. Play*

In music or music theory, the **supertonic** is the second degree or note of a diatonic scale, one step above the tonic.[1] In music theory, the **supertonic chord** may be symbolized by the Roman numeral **ii** in a major scale, indicating that the chord is a minor chord (for example, D-F-A in C major), or **ii°** in a natural minor scale, indicating that the chord is a diminished chord (for example, D-F-A♭ in C natural minor), if in second inversion a six-four chord (A♭-D-F), and if the third is raised an augmented sixth chord (A♭-F♯). If in major or minor, through the lowering of the second scale degree (also the sixth in major), the chord is major (D♭-F-A♭) then it is a Neapolitan 6th chord, N^{6} or ♭II^{6}. The supertonic may be raised as part of the common-tone diminished seventh chord, ♯ii^{ø7}.



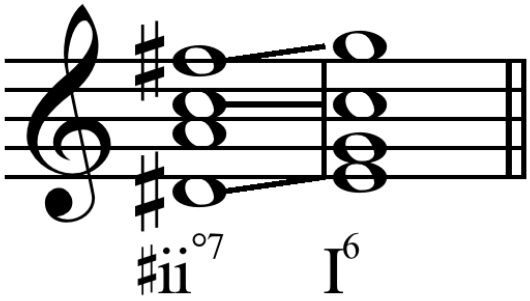
*The similarity between the subdominant and supertonic chords is easily seen and heard through the **supertonic seventh chord**, **ii7**, Play .*



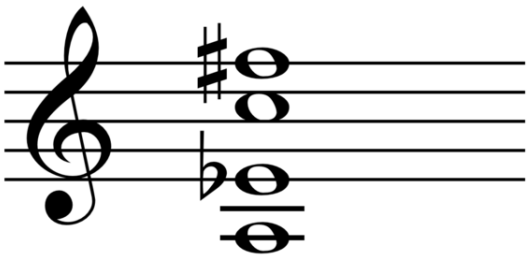
The French sixth chord; distinguishing tone highlighted in blue. Play

One variant of the supertonic seventh chord is the supertonic diminished seventh[2] with the raised supertonic, which equals the lowered third through enharmonic equivalence (in C: D♯=E♭).

In C Major: A Neapolitan sixth chord in first inversion contains an interval of a sixth between F and D♭ (Play).



Common-tone diminished seventh chord Play .



Supertonic diminished seventh chord in C Play .

Pre-dominant (sometimes called "sub-dominant") chords are chords which distinguish chord V as a goal of motion (as opposed to it acting as an embellishing chord within a phrase) they create gravity and harmonic motion towards dominant harmony, and form a fundamental aspect of western tonal music.

The supertonic chord is known as a pre-dominant chord, as it is one of the unique chords which has a natural tendency to gravitate towards chord V and strengthen V as a goal of motion. The supertonic chord lies a fifth above chord V. Descending fifths are a strong basis for harmonic motion and harmonic motion through intervals of fifths is a natural way for chords to progress to one another; the supertonic is one of the strongest pre-dominants and approaches chord V from above through a descending 5th. It is preferable to avoid chord two in root position in the minor mode due to the harsh quality of its diminished intervals, ii6 is a much nicer alternative. This is less of an issue if the chord contains a chordal seventh; indeed, root-position diminished seventh chords are quite common.

Adding a chordal seventh to the supertonic (minor or diminished) does nothing to interfere with its pre-dominant qualities, but rather intensifies their pre-dominant function and also increases harmonic intensity and motion towards dominant harmony. Supertonic seventh chords are such intense pre-dominant chords because they outline the leading note contained in chord V with a dissonance.

"Supertonic" also refers to a relationship of musical keys. For example, relative to the key of C major, the key of D major (or D minor) is the supertonic. Modulation (change of key) to the supertonic is relatively common (by far the most common modulation in modern popular music), though in classical music it is more common to modulate to the dominant or other keys.

In German theory derived from Hugo Riemann, the supertonic is considered the subdominant parallel: Sp/T in major though sP/T in minor (A♭M).

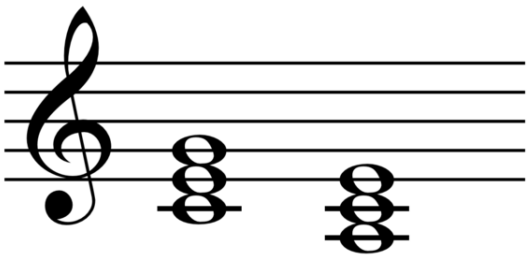
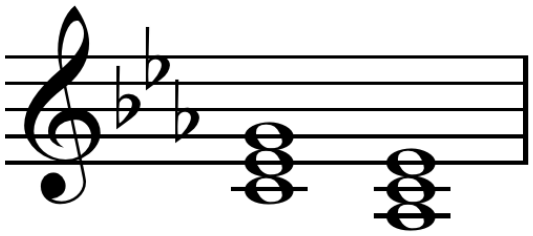
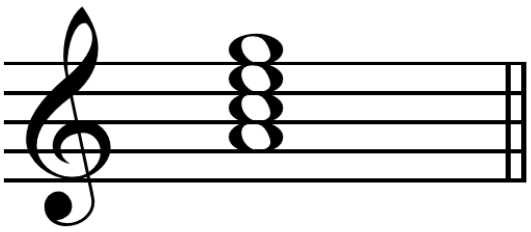
Submediant



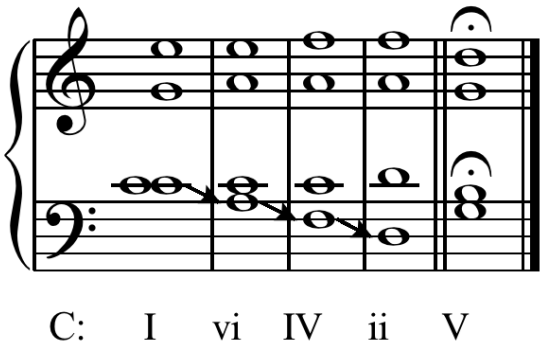
Tonic and submediant (tonic parallel) in C major: CM and Am chords Play .



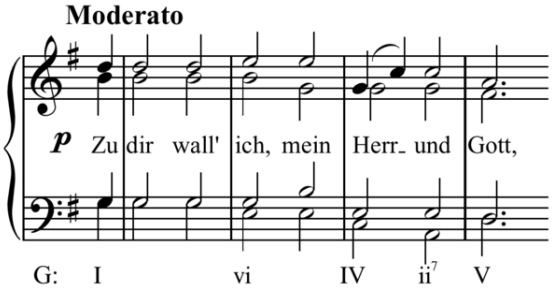
Tonic and submediant in C minor: Cm and A♭M chords Play .



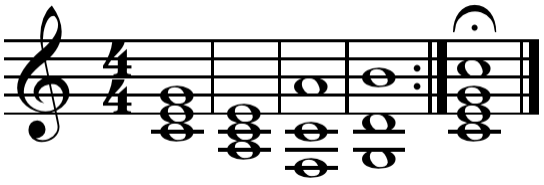
*Minor seventh chord on a Play . vi^7 or **submediant seventh chord** in C major.*



Chord progression from the tonic to supertonic, resolving to the dominant[1] Play .



Wagner - Tannhauser, Zu dir wall'ich[1] Play .

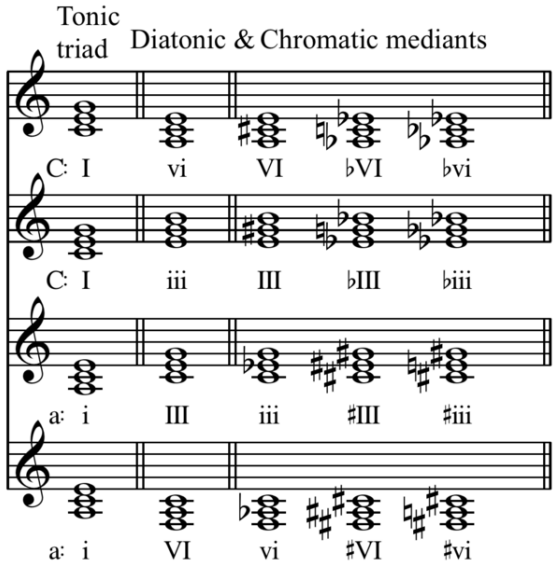


vi in I-vi-IV-V-I (50s progression) on C, play

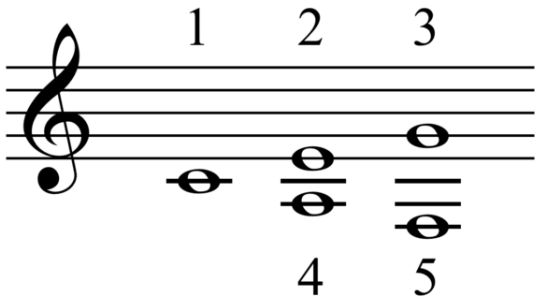
In music, the **submediant** is the sixth scale degree of the diatonic scale, the 'lower mediant' halfway between the tonic and the subdominant or 'lower dominant'.[3] It is also the third factor of the subdominant (IV) triad. It is occasionally called **superdominant**, being above the dominant.

In music theory, the submediant chord is symbolized by the Roman numeral VI if it is major or vi if it is minor.[4]

For example, in the C major scale (white keys on a piano, starting on C), the submediant is the note A; and the submediant chord is A-minor consisting of the notes A, C, and E. Therefore, Am is the vi chord in the C major scale. Since the submediant is minor it may provide contrast with major chords, frequently in a sequence of descending thirds (I, vi, IV, ii | V in root position or first inversion).[1] Further, in the A natural minor scale (same

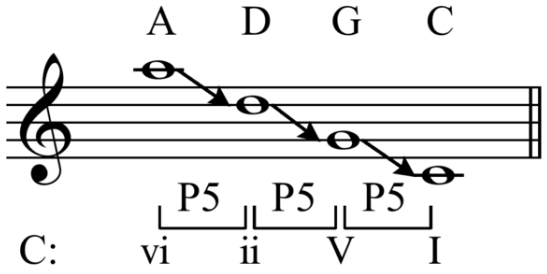


Chromatic mediants in C major and a minor.



"1. Tonic, 2. Mediant, i.e., half-way to dominant, 3. Dominant, 4.Sub-Mediant, i.e., half-way to sub-dominant, 5. Sub-Dominant."[2]

white keys, now starting on A), the submediant is the note F; and the submediant chord is F (or F-major) consisting of the notes F, A, and C. Therefore, F is the VI chord in the A (natural) minor scale.



Submediant in chain of fifths[1] *Play* .

The submediant is also in the same relationship to the supertonic as the supertonic is to the dominant, resulting in a descending series of perfect fifths known as an extended dominant relationship.[1] See: predominant and circle progression.

Submediant voice leading: the third may be doubled[5] *Play* .

The submediant is usually preceded by the mediant, tonic, or dominant and succeeded by supertonic, dominant, or subdominant.[6] The submediant function is easily explained in reference to jazz music, where it is used in the "ice cream change" or "Blues for Alice" progression, which moves from the tonic through the submediant on the way to the ubiquitous ii-V-I Jazz sequence (part of the cycle of fifths). The progression's consistency is amplified by the submediant's fifth-relationship above the supertonic. This submediant role—in which it essentially extends from the tonic as a way of passing to a subdominant (IV) or supertonic (II) harmony, is as common in popular and classical music as it is in jazz, or any other musical language related to Western European tonality.

Both vi^6 and iii^6 are weak and rarely independent, being either linear chords or with the third or sixth scale degree as a nonharmonic tone.[7]

"Submediant" also refers to a relationship of musical keys. For example, relative to the key of C major, the key of A major (or A minor) is the submediant. Modulation (change of key) to the submediant is relatively rare, compared with, for instance, modulation to the dominant, and gives a feeling of relaxation. Susan McClary says that modulation to the lowered submediant (in C: A♭) represents a dream-like state of escape.

In German theory derived from Hugo Riemann the submediant in major is considered the tonic parallel (US relative), Tp, and the minor the subdominant parallel, sP.

Chromatic submediants are, like all chromatic mediants, chords whose roots are related by a major third or minor third, contain one common tone, and share the same quality, i.e. major or minor. They may be altered chords.

In rock and popular music, VI in minor often uses the chromatically lowered fifth scale degree as its seventh, VI7, for example as in Eric Clapton's clearly minor mode "I Shot The Sheriff".[8]

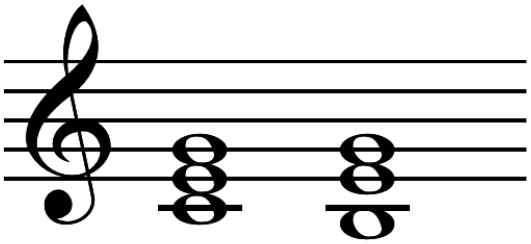
Chapter 18

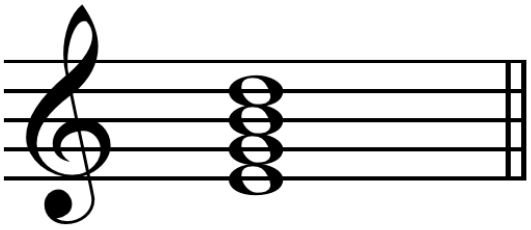
Mediant

For mediant in mathematics, see Mediant (mathematics).

In music, the **mediant** (*Latin*: to be in the middle[3])



Tonic and mediant (dominant parallel or tonic counter parallel) in C major: CM and Em chords Play .

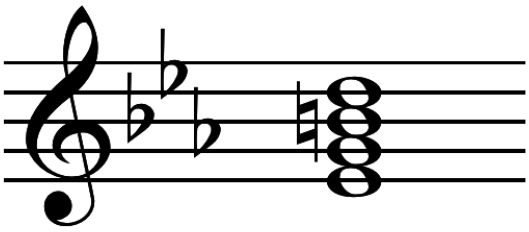


*Minor seventh chord on e Play . iii^{7} or **mediant seventh chord** in C major.*

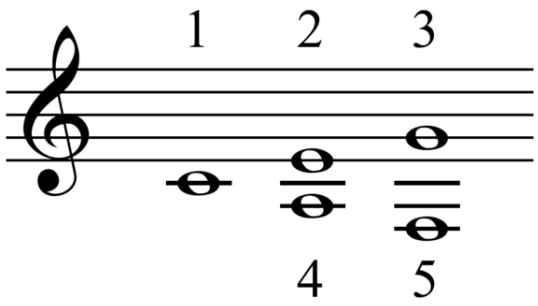
♭III^{+} Play .

is the third scale degree of a diatonic scale, being the note halfway between the tonic and the dominant.[4] Similarly, the submediant is halfway between the tonic and subdominant.[5] The fifth note is almost always a perfect fifth, while the third note can equally be a minor or major third.

♭III^{+} as dominant substitute Play .



III+ $^{7}_{M}$ chord in C harmonic or ascending melodic minor[1] Play .



"1. Tonic, 2. Mediant, i.e., half-way to dominant, 3. Dominant, 4.Sub-Mediant, i.e., half-way to sub-dominant, 5. Sub-Dominant."[2]

Schenkerian analysts consider this scale degree as expansion of the Tonic since they have two common tones.[6] On the other hand, in German theory derived from Hugo Riemann the mediant in major is considered the dominant parallel, Dp, and in minor the tonic parallel, tP.

In Roman numeral analysis, the mediant chord can take

several forms. In major scales, the mediant chord is minor and is noted with the Roman numeral **iii**. In a natural minor scale, the mediant occurs as a major chord, noted with the Roman numeral **III**. In harmonic minor scales and ascending melodic minor scales, the seventh scale degree is raised by a half-step from a subtonic to a leading tone, creating an augmented mediant chord, noted with the Roman numeral **(♭)III**$^{+}$.

For example, in the C major scale (white keys on a piano, starting on C), the mediant is the note E; and the mediant chord is E-minor consisting of the notes E, G, and B. Therefore, Em is the iii chord in the C major scale. Also, in the A natural minor scale (same white keys, but now starting on A), the mediant is the note C; and the mediant chord is C (or C-major) consisting of the notes C, E, and G. Therefore, C is the III chord in the A (natural) minor scale. However, if the harmonic minor scale is used, G would be raised to G♯, changing the C chord to Caug, consisting of the notes C, E, and G♯. Therefore, Caug is the III^{+} chord in the A harmonic minor scale.

"Mediant" also refers to a relationship of musical keys. For example, relative to the key of A (natural) minor, the key of C major is the mediant, and often serves as a mid-way point between I and V (hence the name). Tonicization or modulation to the mediant is quite common in pieces written in the minor mode, and usually serves as the second theme group in sonata forms, since it is very easy to tonicize III in minor (no need to alter notes). Tonicization of III in major is quite rare in classical harmony, compared with, say, modulation to the V in major, but mediant tonicization in major is an important feature of late romantic music.

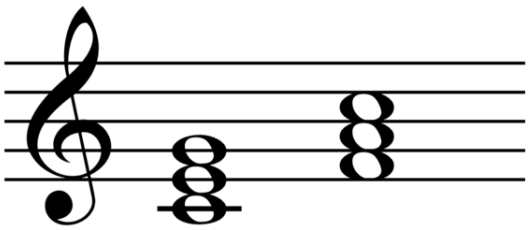
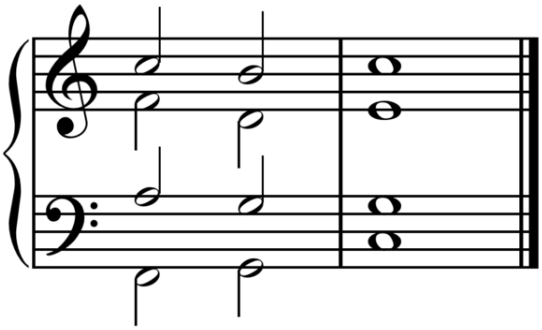
Chapter 19

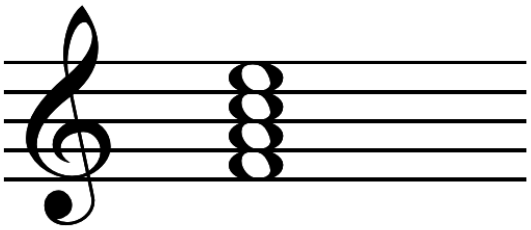
Subdominant



Tonic and subdominant in C Play . C major and F major chords.



Subdominant (IV) in IV-V-I progression, in C Play

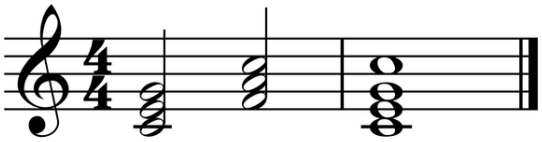


*Major seventh chord on F. Play IV7 M,[1] or **subdominant seventh** in C major.*

In music, the **subdominant** is the technical name for the fourth tonal degree of the diatonic scale. It is so called because it is the same distance "below" the tonic as the dominant is above the tonic - in other words, the tonic is the dominant of the subdominant.[2] It also happens to be the note immediately "below" the dominant.[3] In the C major scale (white keys on a piano, starting on C), the subdominant is the note F; and the subdominant chord uses the notes F, A, and C. In music theory, Roman numerals are used to symbolize the subdominant chord as 'IV' if it is within the major mode (because it is a major triad, for example F-A-C in C major) or 'iv' if it is within the minor mode (because it is a minor triad, for example F-A♭-C in C minor).

> In very much conventionally tonal music, harmonic analysis will reveal a broad prevalence of the primary (often triadic) harmonies: tonic, dominant, and subdominant (i.e., I and its chief auxiliaries a 5th removed), and especially the first two of these.
> —Berry (1976)[4]

Because ii_6, ii6
5, and neapolitan sixth chords contain the fourth scale degree in the bass, they are also considered subdominant harmonies because they substitute for the same harmonic purpose as chords built on the fourth scale degree.



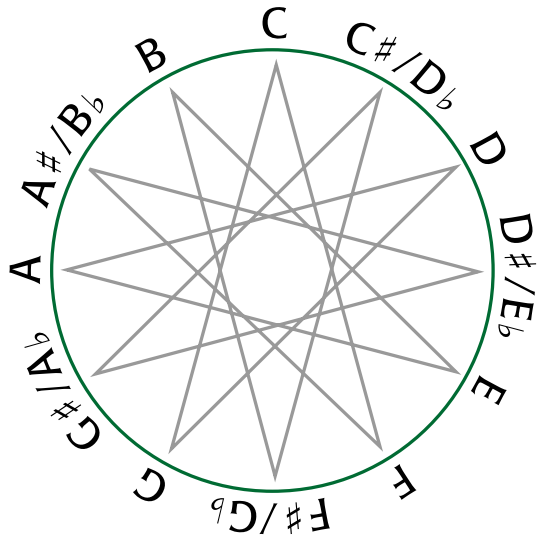
Subdominant (IV) in I-IV-I progression, in C Play

A cadential subdominant chord followed by a tonic chord (the chord of the key of the piece) produces the so-called "plagal" (or "Amen") cadence.

"Subdominant" also refers to a relationship of musical keys. For example, relative to the key of C major, the key of F major is the subdominant. Music which modulates (changes key) often modulates into the subdominant when the leading tone is lowered by a half step to the subtonic (B to B♭ in the key of C). Modulation into the subdominant key often creates a sense of musical relaxation; as opposed to modulation into dominant (fifth note of the scale), which increases tension.

In sonata form, the subdominant key plays a subordinate though still crucial role: typically, in the recapitulation,

there is a section written in the subdominant key, occurring at the point corresponding to the location in the exposition where the music modulated into the dominant key. The use of the subdominant in this location often serves as a way of keeping the rest of recapitulation in the tonic.



The circle of fifths drawn within the chromatic circle as a star dodecagram.[5] In C, the tonic would be on the top with subdominant and dominant at the bottom both equidistant to the tonic.

As with other chords which may or tend to precede the dominant the **subdominant** diatonic function acts as a dominant preparation or predominant. In theories after Hugo Riemann it is considered to balance the dominant around the tonic (being as far below the tonic as the dominant is above).

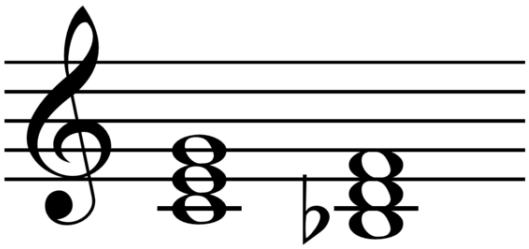
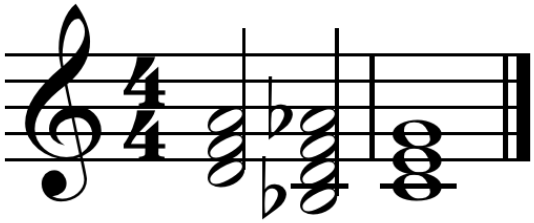
Chapter 20

Subtonic



Tonic and subtonic in C Play . C major and B♭ major chords.



"'Backdoor' ii-V" in C: ii-♭VII^7-I Play

In music, the **subtonic** is the scale degree below the tonic or, more specifically, the **flattened seventh** (**♭VII**): the lowered or minor seventh degree of the scale, a whole step below the tonic, as opposed to the leading tone, which is only a half step below the tonic.[1] The distinction between leading tone and subtonic has been made by theorists since at least the second quarter of the 20th century.[2]

The subtonic appears in three forms: as the scale degree, ♭ $\hat{7}$, melodically and as the chord ♭VII in both ♭VII-I cadence and in modulations harmonically.[3] The word is also used as an English translation of *subtonium*, the Latin term used in Gregorian chant theory for the similar usage of a tone one whole step below the mode final in the Dorian, Phrygian, and Mixolydian modes.[4]

For example, in the A minor scale (white keys on a piano, starting on A), the subtonic is the note G (in C major this would be B♭); and the subtonic triad consists of the notes G, B, and D (in C: B♭-D-F). In music theory, the subtonic chord is symbolized with the Roman numeral ♭VII for a major triad built on the note, or ♭vii for a minor triad; in a minor key, the flat symbol is sometimes omitted by some theorists because the subtonic note appears in the natural minor scale, but the flat symbol is usually used for the major scale because the subtonic is a non-scale note.

A I chord, C major, followed by a ♭VII chord, B♭ major, borrowed from the parallel minor, C minor, with the key signature of C major followed by C minor shown.

In jazz, the flattened seventh is also used as a substitute for the dominant, V, especially in the Backdoor cadence,[5] ii-♭VII7-I, where the subtonic is used for the dominant seventh. ♭VII is in this case a pivot chord borrowed from the parallel minor (its dominant seventh). V7 and **♭VII7**, the **subtonic seventh chord**, have two common tones, in C: GB**DF** and B♭**DF**A♭.

However, while, "the leading-tone/tonic relationship is axiomatic to the definition of common practice tonality," especially cadences and modulations, in popular music and rock a diatonic scalic leading tone (i.e., ♮ $\hat{7}$ - $\hat{1}$) is often absent.[6] In popular music, rather than "departures" or "aberrant," the "use of the 'flattened' diatonic seventh scale degree...should not even be viewed as *departures*".[7]

> In very much conventionally tonal music, harmonic analysis will reveal a broad prevalence of the primary (often triadic) harmonies: tonic, dominant, and subdominant (i.e., I and its chief auxiliaries a 5th removed), and especially the first two of these.
> —Berry (1976)[5]

In music, the **tonic** is the first scale degree of a diatonic scale and the tonal center or final resolution tone.[4] The triad formed on the tonic note, the **tonic chord**, is thus the most significant chord. More generally, the tonic is the pitch upon which all other pitches of a piece are hierarchically referenced. Scales are named after their tonics, thus the tonic of the scale of C is the note C.

The tonic is often confused with the root, which is the reference note of a chord, rather than that of the scale. It is also represented with the Roman numeral I.

21.1 Importance and function

In western European tonal music of the 18th and 19th centuries, the tonic center was the most important of all

the different tone centers which a composer used in a piece of music, with most pieces beginning and ending on the tonic, usually modulating to the dominant (the fifth above the tonic, or the fourth note down from the tonic) in between.

Two parallel keys have the same tonic. For example, in both C major and C minor, the tonic is C. However, relative keys (two different scales that share a key signature) have different tonics. For example, C major and A minor share a key signature that feature no sharps or flats, despite having different tonic pitches (C and A, respectively).

Tonic may be reserved exclusively for use in tonal contexts while ***tonal center*** and/or ***pitch center*** may be used in post- and atonal music: "For purposes of non-tonal centric music, it might be a good idea to have the term 'tone center' refer to the more general class of which 'tonics' (or tone centers in tonal contexts) could be regarded as a subclass."[6] Thus a pitch center may function referentially or contextually in an atonal context, often acting as axis or line of symmetry in an interval cycle.[7] ***Pitch centricity*** was coined by Arthur Berger in his "Problems of Pitch Organization in Stravinsky".[8]

The tonic diatonic function includes four separate activities or roles as the principal goal tone, initiating event, generator of other tones, and the stable center neutralizing the tension between dominant and subdominant.

Chapter 22

Chord (music)

Instruments and voices playing and singing different notes create chords.

> *This article describes pitch simultaneity and harmony in music. For other meanings of the word, see Chord.*

A **chord**, in music, is any harmonic set of three or more notes that is heard as if sounding simultaneously.[1][2] These need not actually be played together: arpeggios and broken chords may, for many practical and theoretical purposes, constitute chords. Chords and sequences of chords are frequently used in modern Western, West African[3] and Oceanian[4] music, whereas they are absent from the music of many other parts of the world.[5]

The most frequently encountered chords are triads, so called because they consist of three distinct notes: further notes may be added to give seventh chords, extended chords, or added tone chords. The most common chords are the *major* and *minor triads* and then the *augmented* and *diminished triads*. The descriptions *major*, *minor*, *augmented*, and *diminished* are sometimes referred to collectively as chordal *quality*. Chords are also commonly classed by their root note—so, for instance, the chord **C** major may be described as a triad of major quality built upon the note **C**. Chords may also be classified by inversion, the order in which the notes are stacked.

A series of chords is called a chord progression. Although any chord may in principle be followed by any other chord, certain patterns of chords have been accepted as establishing key in common-practice harmony. To describe this, chords are numbered, using Roman numerals, upwards from the key-note[6] *(See diatonic function)*. Common ways of notating or representing chords[7] in western music other than conventional staff notation include Roman numerals, figured bass (much used in the Baroque era), macro symbols (sometimes used in modern musicology), and various systems of chord charts typically found in the lead sheets used in popular music to lay out the sequence of chords so that the musician may play accompaniment chords or improvise a solo.

22.1 Definition and history

Main article: Harmony

The English word *chord* derives from Middle English *cord*, a shortening of *accord*[8] in the original sense of *agreement* and later, *harmonious sound*.[9] A sequence of chords is known as a chord progression or harmonic progression. These are frequently used in Western music.[5] A chord progression "aims for a definite goal" of establishing (or contradicting) a tonality founded on a key, root

Mussorgsky's Pictures at an Exhibition *"Promenade", is a piece showing an explicit chord progression.(Nattiez 1990, p. 218) Play*

or tonic chord.[6] The study of harmony involves chords and chord progressions, and the principles of connection that govern them.[10]

Ottó Károlyi[11] writes that, "Two or more notes sounded simultaneously are known as a chord," though, since instances of any given note in different octaves may be taken as the same note, it is more precise for the purposes of analysis to speak of distinct *pitch classes*. Furthermore, as three notes are needed to define any common chord, three is often taken as the minimum number of notes that form a definite chord. Hence Andrew Surmani, for example, (2004, p. 72) states, "When three or more notes are sounded together, the combination is called a chord." George T. Jones (1994, p. 43) agrees: "Two tones sounding together are usually termed an *interval*, while three or mores tones are called a *chord*." According to Monath (1984, p. 37); "A chord is a combination of three or more tones sounded simultaneously," and the distances between the tones are called intervals. However sonorities of two pitches, or even single-note melodies, are commonly heard as *implying* chords.[12]

Since a chord may be understood as such even when all its notes are not simultaneously audible, there has been some academic discussion regarding the point at which a group of notes may be called a *chord*. Jean-Jacques Nattiez (1990, p. 218) explains that, "We can encounter 'pure chords' in a musical work," such as in the *Promenade* of Modest Mussorgsky's *Pictures at an Exhibition* but, "Often, we must go from a textual given to a more *abstract* representation of the chords being used," as in Claude Debussy's *Première Arabesque*.

Upper stave: Claude Debussy's Première Arabesque. *The chords on the lower stave are constructed from the notes in the actual piece, shown on the upper stave. Play*

In the medieval era, early Christian hymns featured organum (which used the simultaneous perfect intervals of a fourth, a fifth, and an octave[13]), with chord progressions and harmony an incidental result of the emphasis on melodic lines during the medieval and then Renaissance (15-17th centuries).[7][14]

The Baroque period, the 17th and 18th centuries, began to feature the major and minor scale based tonal system and harmony, including chord progressions and circle progressions.[7] It was in the Baroque period that the accompaniment of melodies with chords was developed, as in figured bass,[14] and the familiar cadences (perfect authentic, etc.).[15] In the Renaissance, certain dissonant sonorities that suggest the dominant seventh occurred with frequency.[16] In the Baroque period the dominant seventh proper was introduced, and was in constant use in the Classical and Romantic periods.[16] The leading-tone seventh appeared in the Baroque period and remains in use.[17] Composers began to use nondominant seventh chords in the Baroque period. They became frequent in the Classical period, gave way to altered dominants in the Romantic period, and underwent a resurgence in the Post-Romantic and Impressionistic period.[18]

The Romantic period, the 19th century, featured increased chromaticism.[7] Composers began to use secondary dominants in the Baroque, and they became common in the Romantic period.[19] Many contemporary popular Western genres continue to rely on simple diatonic harmony, though far from universally:[20] notable exceptions include the music of film scores, which often use chromatic, atonal or post-tonal harmony, and modern jazz (especially circa 1960), in which chords may include up to seven notes (and occasionally more).[21]

Triads consist of three notes; the *root* or *first* note, the *third*, and the *fifth*.[22] For example the **C** major scale consists of the notes **C D E F G A B**: a triad can be constructed on any note of such a major scale, and all are minor or major except the triad on the seventh or leading-tone, which is a diminished chord. A triad formed using the note **C** itself consists of **C** (the root note), **E** (the third note of the scale) and **G** (the fifth note of the scale). The interval from **C** to **E** is of four semitones, a major third, and so this triad is called **C** Major. A triad formed upon the same scale but with **D** as the root note, **D** (root), **F** (third), **A** (fifth), on the other hand, has only three semitones between the root and third and is called **D** minor, a minor triad.

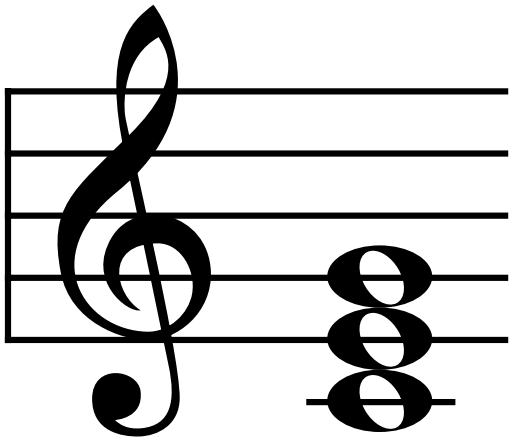
22.2 Notation

See also: Chord names and symbols (popular music)

Chords can be represented in various ways. The most common notation systems are:[7]

1. Plain staff notation, used in classical music (see figure).

2. Roman numerals, commonly used in harmonic analysis to denote the scale step on which the chord is built.[6] See: Roman numeral analysis.



C Major triad represented in staff notation.

3. Figured bass, much used in the Baroque era, uses numbers added to a bass line written on staff (music), to enable keyboard players to improvise chords with the right hand while playing the bass with their left.

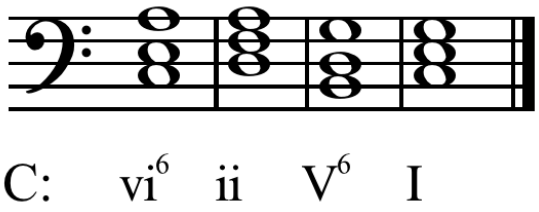
4. Macro symbols, sometimes used in modern musicology, to denote chord root and quality.

5. Various chord names and symbols used in popular music lead sheets, fake books, and chord charts, to quickly lay out the harmonic groundplan of a piece so that the musician may improvise, jam, or vamp on it.

22.2.1 Roman numerals

Main article: Roman numeral analysis

While scale degrees are typically represented with Arabic numerals, the triads that have these degrees as their roots are often identified by Roman numerals. In some conventions (as in this and related articles) upper-case Roman numerals indicate major triads while lower-case Roman numerals indicate minor triads: other writers, (e.g. Schoenberg) use upper case Roman numerals for both major and minor triads. Some writers use upper-case Roman numerals to indicate the chord is diatonic in the major scale, and lower-case Roman numerals to indicate that the chord is diatonic in the minor scale. Diminished triads may be represented by lower-case Roman numerals with a degree symbol. Roman numerals can also be used in stringed instrument notation to indicate the position or string to play.

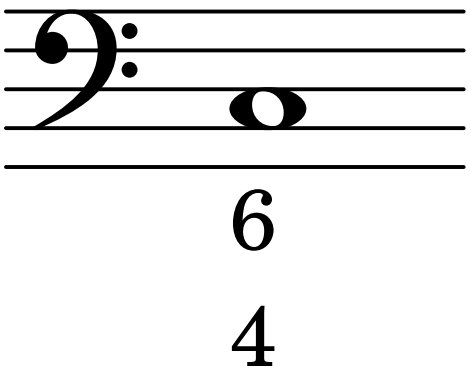


vi-ii-V-I in C[23] *Play* .

22.2.2 Figured bass notation

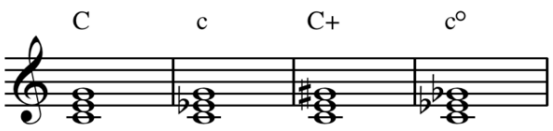
Main article: Figured bass

Figured bass or thoroughbass is a kind of musical notation used in almost all Baroque music, though rarely in modern music, to indicate harmonies in relation to a conventionally written bass line. Figured bass is closely associated with basso continuo accompaniment. Added numbers and accidentals beneath the staff indicate at the intervals to play, the numbers stand for the number of scale steps above the written note to play the figured notes.



In the illustration the bass note is a **C**, and the numbers 4 and 6 indicate that notes a fourth and a sixth above, that is **F** and **A**, should be played, giving the second inversion of the **F** major triad.

22.2.3 Macro analysis



Macro analysis for triads on C.

Main article: Macro analysis

Macro analysis uses upper-case and lower-case letters to indicate the roots of chords, followed by symbols that specify the chord quality.[7]

22.2.4 Tabular notation

Main article: Chord names and symbols (popular music)

In most genres of popular music, including jazz, pop, and rock, a chord name and the corresponding symbol are typically composed of one or more of the following parts:

1. The root note (e.g. C).
2. The chord quality (e.g. major, maj, or M).
3. The number of an interval (e.g. seventh, or 7), or less often its full name or symbol (e.g. major seventh, maj7, or M7).
4. The altered fifth (e.g. sharp five, or ♯5).
5. An additional interval number (e.g. add 13 or add13), in added tone chords.

For instance, the name C augmented seventh, and the corresponding symbol Caug7, or C+7, are both composed of parts 1, 2, and 3.

None of these parts, except for the root, directly refer to the notes forming the chord, but to the intervals they form with respect to the root. For instance, Caug7 is formed by the notes C-E-G♯-B♭. However, its name and symbol refer only to the root note C, the augmented (fifth) interval from C to G♯, and the (minor) seventh interval from C to B♭. The interval from C to E (a major third) sets the chord quality (major). A set of decoding rules is applied to deduce the missing information.

Chord qualities are related with the qualities of the component intervals that define the chord. The main chord qualities are:

- Major, and minor.
- Augmented, diminished, and half-diminished.
- Dominant.

Some of the symbols used for chord quality are similar to those used for interval quality:

- **m**, or **min** for minor,
- **M**, **maj**, or no symbol (see rule 2 below) for major,
- **aug** for augmented,
- **dim** for diminished.

In addition, however,

- **Δ** is sometimes used for major,[24] instead of the standard M, or maj,
- **−** is sometimes used for minor, instead of the standard m or min,
- **+**, or **aug**, is used for augmented (**A** is not used),
- **º**, °, **dim**, is used for diminished (**d** is not used),
- **ø**, or **Ø** is used for half diminished,
- **dom** is used for dominant.

22.3 Characteristics

Every chord has certain characteristics, which include:

- Number of pitch classes (distinct notes without respect to octave) that constitute the chord.
- Scale degree of the root note
- Position or inversion of the chord
- General type of intervals it appears constructed from—for example seconds, thirds, or fourths
- Counts of each pitch class as occur between all combinations of notes the chord contains

22.3.1 Number of notes

Two-note combinations, whether referred to as chords or intervals, are called *dyads*. Chords constructed of three notes of some underlying scale are described as *triads*. Chords of four notes are known as *tetrads*, those containing five are called *pentads* and those using six are *hexads*. Sometimes the terms *trichord*, *tetrachord*, *pentachord*, and *hexachord* are used—though these more usually refer to the pitch classes of any scale, not generally played simultaneously. Chords that may contain more than three notes include pedal point chords, dominant seventh chords, extended chords, added tone chords, clusters, and polychords.

Polychords are formed by two or more chords superimposed.[25] Often these may be analysed as extended chords *(See: tertian, altered chord, secundal chord, quartal and quintal harmony and Tristan chord)*. For example G^7(♯11♭9) (G-B-D-F-A♭-C♯) is formed from G major (G-B-D) and D♭ major (D♭-F-A♭).[26] A nonchord tone is a dissonant or unstable tone that lies outside the chord currently heard, though often resolving to a chord tone.[27]

22.3.2 Scale degree

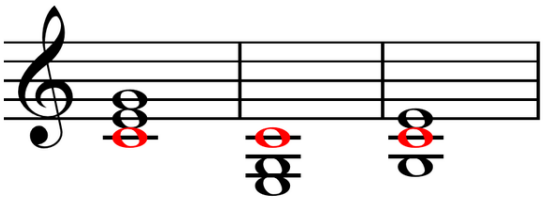
In the key of **C major** the first degree of the scale, called the tonic, is the note **C** itself, so a **C** major chord, a triad built on the note **C**, may be called the *one chord* of that

C major scale play

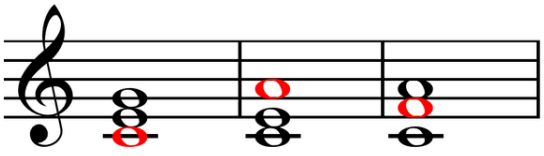
key and notated in Roman numerals as **I**. The same **C** major chord can be found in other scales: it forms chord **III** in the key of **A minor** (**A**-*B*-**C**) and chord **IV** in the key of **G major** (**G**-*A*-*B*-**C**). This numbering lets us see the job a chord is doing in the current key and tonality.

Many analysts use lower-case Roman numerals to indicate minor triads and upper-case for major ones, and *degree* and *plus* signs (° and +) to indicate diminished and augmented triads respectively. Otherwise all the numerals may be upper-case and the qualities of the chords inferred from the scale degree. Chords outside the scale can be indicated by placing a flat/sharp sign before the chord — for example, the chord of **E** flat major in the key of **C** major is represented by **♭III**. The tonic of the scale may be indicated to the left (e.g. **F♯:**) or may be understood from a key signature or other contextual clues. Indications of inversions or added tones may be omitted if they are not relevant to the analysis. Roman numerals indicate the root of the chord as a scale degree within a particular major key as follows:

22.3.3 Inversion



Root position, first inversion, and second inversion C major chords Play root position C major chord , Play first inversion C major chord , or Play second inversion C major chord . Chord roots (all the same) in red.



Root position, first inversion, and second inversion chords over C bass Play root position C major chord , Play first inversion A minor chord , or Play second inversion F major chord . Chord roots in red.

Main article: Inversion (music)

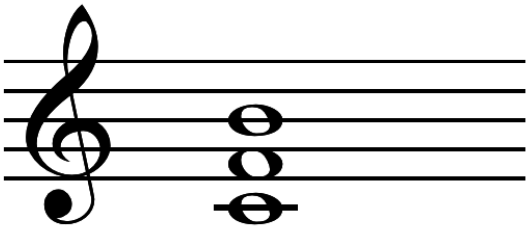
In the harmony of Western art music a chord is in *root position* when the tonic note is the lowest in the chord, and the other notes are above it. When the lowest note is not the tonic, the chord is *inverted*. Chords, having many constituent notes, can have many different inverted positions as shown below for the C major chord:

Further, a four-note chord can be inverted to four different positions by the same method as triadic inversion. Where guitar chords are concerned the term "inversion" is used slightly differently; to refer to stock fingering "shapes".[28]

22.3.4 Secundal, tertian, and quartal chords

See also: Secundal, Tertian, Quartal and quintal harmony and Mixed-interval chord

Many chords are a sequence of ascending notes sepa-



Quartal chord: C-F-B chord[29] Play .

rated by intervals of roughly the same size. Chords can be classified into different categories by this size:

- Tertian chords can be decomposed into a series of (major or minor) thirds. For example, the C major triad (C-E-G) is defined by a sequence of two intervals, the first (C-E) being a major third and the second (E-G) being a minor third. Most common chords are tertian.

- Secundal chords can be decomposed into a series of (major or minor) seconds. For example, the chord C-D-E♭ is a series of seconds, containing a major second (C-D) and a minor second (D-E♭).

- Quartal chords can be decomposed into a series of (perfect or augmented) fourths. Quartal harmony normally works with a combination of perfect and augmented fourths. Diminished fourths are enharmonically equivalent to major thirds, so they are uncommon.[30] For example, the chord C-F-B is a series of fourths, containing a perfect fourth (C-F) and an augmented fourth/tritone (F-B).

These terms can become ambiguous when dealing with non-diatonic scales, such as the pentatonic or chromatic scales. The use of accidentals can also complicate the terminology. For example, the chord B♯-E-A♭ appears to

be a series of diminished fourths (B♯-E and E-A♭) but is enharmonically equivalent to (and sonically indistinguishable from) the chord C-E-G♯, which is a series of major thirds (C-E and E-G♯).

22.3.5 Harmonic Content

The notes of a chord form intervals with each of the other notes of the chord in combination. A 3-note chord has 3 of these harmonic intervals, a 4-note chord has 6, a 5-note chord has 10, a 6-note chord has 15.[31] The absence, presence, and placement of certain key intervals plays a large part in the sound of the chord, and sometimes of the selection of the chord that follows.

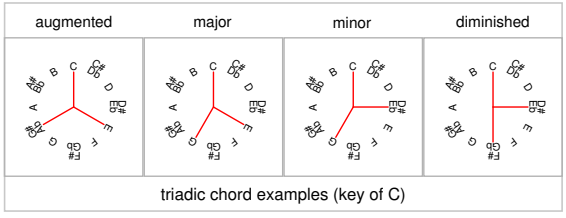
A chord containing tritones is called tritonic; one without tritones is atritonic. Harmonic tritones are an important part of Dominant seventh chords, giving their sound a characteristic tension, and making the tritone interval likely to move in certain stereotypical ways to the following chord.[32]

A chord containing semitones, whether appearing as Minor seconds or Major sevenths, is called hemitonic; one without semitones is anhemitonic. Harmonic semitones are an important part of Major seventh chords, giving their sound a characteristic high tension, and making the harmonic semitone likely to move in certain stereotypical ways to the following chord.[33] A chord containing Major sevenths but no Minor seconds is much less harsh in sound than one containing Minor seconds as well.

Other chords of interest might include the

- Diminished chord, which has many Minor thirds and no Major thirds, many Tritones but no Perfect fifths
- Augmented chord, which has many Major thirds and no Minor thirds or Perfect fifths
- Dominant seventh flat five chord, which has many Major thirds and Tritones and no Minor thirds or Perfect fifths

22.4 Triads

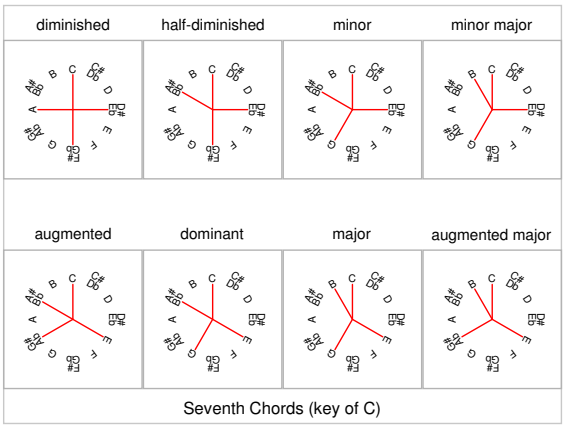


Pitch constellations of triads

Main article: Triad (music)
See also: Jazz and pop notation for triads

Triads, also called *triadic chords*, are tertian chords (see above) with three notes. The four basic triads are described below.

22.5 Seventh chords



Pitch constellations of seventh chords.

Main article: Seventh chord
See also: Jazz and pop notation for seventh chords

Seventh chords are tertian chords (see above), constructed by adding a fourth note to a triad, at the interval of a third above the fifth of the chord. This creates the interval of a seventh above the root of the chord, the next natural step in composing tertian chords. The seventh chord on the fifth step of the scale (the dominant seventh) is the only one available in the major scale: it contains all three notes of the diminished triad of the seventh and is frequently used as a stronger substitute for it.

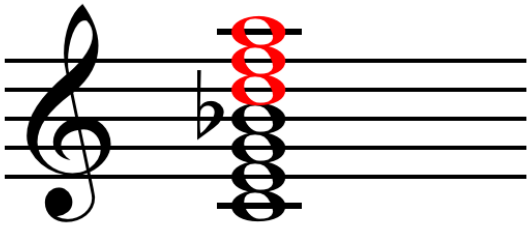
There are various types of seventh chords depending on the quality of both the chord and the seventh added. In chord notation the chord type is sometimes superscripted and sometimes not (e.g. *Dm7*, Dm^7, and D^{m7} are all identical).

22.6 Extended chords

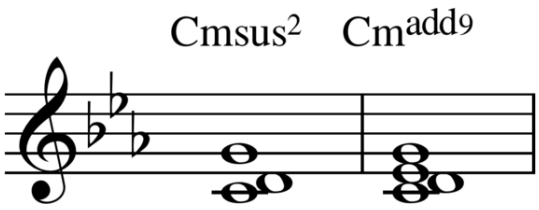
Main article: Extended chord
See also: Jazz and pop notation for extended chords

Extended chords are triads with further tertian notes added beyond the seventh; the ninth, eleventh, and thirteenth chords. After the thirteenth, any notes added in thirds duplicate notes elsewhere in the chord. All seven notes of the scale are present in the chord and adding more notes does not add new pitch classes. Such chords may be constructed only by using notes that lie outside the diatonic seven-note scale (See #Altered chords below).

Other extended chords follow similar rules, so that for example *maj9*, *maj11*, and *maj13* contain major seventh



Dominant thirteenth extended chord: C E G B♭ D F A play . The upper structure or extensions, i.e. notes beyond the seventh, in red.



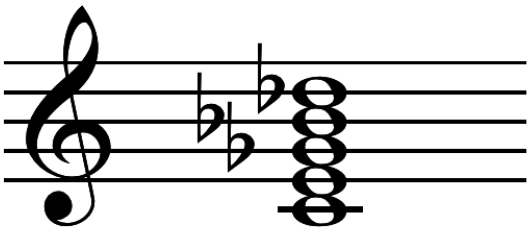
Suspended chord (sus2) and added tone chord (add9) both with D (ninth=second), distinguished by the absence or presence of the third (E♭).[34]

chords rather than dominant seventh chords, while *min9*, *min11*, and *min13* contain minor seventh chords.

22.7 Altered chords

Main article: Altered chord

Although the third and seventh of the chord are al-



Altered chord on C with flat 5th, 7th, and 9th. Play

ways determined by the symbols shown above, the fifth, ninth, eleventh and thirteenth may all be chromatically altered by accidentals (the root cannot be so altered without changing the name of the chord, while the third cannot be altered without altering the chord's quality). These are noted alongside the altered element. Accidentals are most often used with dominant seventh chords. *Altered* dominant seventh chords (C^{7alt}) may have a flat ninth, a sharp ninth, a diminished fifth or an augmented fifth (see Levine's *Jazz Theory*). Some write this as C^{7+9}, which assumes also the flat ninth, diminished fifth and augmented fifth (see Aebersold's *Scale Syllabus*). The augmented ninth is often referred to in blues and jazz as a blue note, being enharmonically equivalent to the flat third or tenth. When superscripted numerals are used the different numbers may be listed horizontally (as shown) or else vertically.

22.8 Added tone chords

Main article: Added tone chord

An added tone chord is a triad chord with an added, non-tertian note, such as the commonly added sixth as well as chords with an added second (ninth) or fourth (eleventh) or a combination of the three. These chords do not include "intervening" thirds as in an extended chord. Added chords can also have variations. Thus *madd9*, *m4* and *m6* are minor triads with extended notes.

Sixth chords can belong to either of two groups. One is first inversion chords and added sixth chords that contain a sixth from the root.[35] The other group is inverted chords in which the interval of a sixth appears above a bass note that is not the root.[36]

The major sixth chord (also called, *sixth* or *added sixth* with the chord notation *6*, e.g., "C6") is by far the most common type of sixth chord of the first group. It comprises a major triad with the added major sixth above the root, common in popular music.[7] For example, the chord C6 contains the notes C-E-G-A. The minor sixth chord (*min6* or *m6*, e.g., "Cm6") is a minor triad with the same added note. For example, the chord Cmin6 contains the notes C-E♭-G-A. In chord notation, the sixth of either chord is always assumed a major sixth rather than a minor sixth, however a minor sixth interval may be indicated in the notation as, for example, "Cm(m6)", or Cm^{m6}.

The augmented sixth chord usually appears in chord notation as its enharmonic equivalent, the seventh chord. This chord contains two notes separated by the interval of an augmented sixth (or, by inversion, a diminished third, though this inversion is rare). The augmented sixth is generally used as a dissonant interval most commonly used in motion towards a dominant chord in root position (with the root doubled to create the octave the augmented sixth chord resolves to) or to a tonic chord in second inversion (a tonic triad with the fifth doubled for the same purpose). In this case, the tonic note of the key is included in the chord, sometimes along with an optional fourth note, to create one of the following (illustrated here in the key of C major):

- Italian augmented sixth: A♭, C, F♯
- French augmented sixth: A♭, C, D, F♯
- German augmented sixth: A♭, C, E♭, F♯

The augmented sixth family of chords exhibits certain peculiarities. Since they are not based on triads, as are sev-

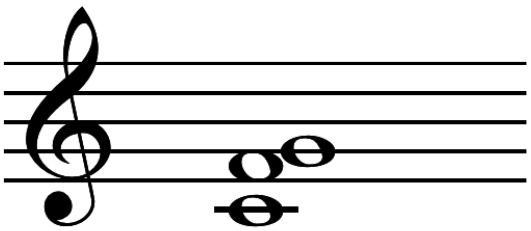
enth chords and other sixth chords, they are not generally regarded as having roots (nor, therefore, inversions), although one re-voicing of the notes is common (with the namesake interval inverted to create a diminished third).[37]

The second group of sixth chords includes inverted major and minor chords, which may be called *sixth* chords in that the *six-three* (6/3) and *six-four* (6/4) chords contain intervals of a sixth with the bass note, though this is not the root. Nowadays this is mostly for academic study or analysis (see figured bass) but the neapolitan sixth chord is an important example; a major triad with a flat supertonic scale degree as its root that is called a "sixth" because it is almost always found in first inversion. Though a technically accurate Roman numeral analysis would be ♭II, it is generally labelled N^6. In C major, the chord is notated (from root position) D♭, F, A♭. Because it uses chromatically altered tones this chord is often grouped with the borrowed chords (*see below*) but the chord is not borrowed from the relative major or minor and it may appear in both major and minor keys.

22.9 Suspended chords

Main article: Suspended chord

A suspended chord, or "sus chord" (sometimes wrongly thought to mean *sustained chord*), is a chord in which the *third* is replaced by either the *second* or the *fourth*. This produces two main chord types: the *suspended second* (sus2) and the *suspended fourth* (sus4). The chords, $\mathbf{C^{sus2}}$ and $\mathbf{C^{sus4}}$, for example, consist of the notes *C D G* and *C F G*, respectively. There is also a third type of suspended chord, in which both the second and fourth are present, for example the chord with the notes *C D F G*.



Sus4 chord on C play

The name *suspended* derives from an early polyphonic technique developed during the common practice period, in which a stepwise melodic progress to a harmonically stable note in any particular part was often momentarily delayed or *suspended* by extending the duration of the previous note. The resulting unexpected dissonance could then be all the more satisfyingly resolved by the eventual appearance of the displaced note. In traditional music theory the inclusion of the *third* in either chord would negate the suspension, so such chords would be called *added ninth* and *added eleventh* chords instead.

In modern layman usage the term is restricted to the displacement of the *third* only and the dissonant *second* or *fourth* no longer needs to be held over (*prepared*) from the previous chord. Neither is it now obligatory for the displaced note to make an appearance at all though in the majority of cases the conventional stepwise resolution to the *third* is still observed. In post-bop and modal jazz compositions and improvisations suspended seventh chords are often used in nontraditional ways: these often do not function as **V** chords, and do not resolve from the fourth to the third. The lack of resolution gives the chord an ambiguous, static quality. Indeed, the third is often played on top of a sus4 chord. A good example is the jazz standard, *Maiden Voyage*.

Extended versions are also possible, such as the *seventh suspended fourth*, which, with root *C*, contains the notes *C F G B♭* and is notated as $\mathbf{C7^{sus4}}$ play . $\mathbf{C^{sus4}}$ is sometimes written $\mathbf{C^{sus}}$ since the sus4 is more common than the sus2.

22.10 Borrowed chords

Main article: Borrowed chord

A borrowed chord is one from a different key than the *home key*, the key of the piece it is used in. The most common occurrence of this is where a chord from the parallel major or minor key is used. Particularly good examples can be found throughout the works of composers such as Schubert.

Borrowed chords from the parallel minor key are commonly found in the Baroque, Classical and Romantic eras.

For instance, for a composer working in the C major key, a major ♭III chord would be borrowed, as this appears only in the C minor key. Although borrowed chords could theoretically include chords taken from any key other than the home key, this is not how the term is used when a chord is described in formal musical analysis.

When a chord is analysed as "borrowed" from another key it may be shown by the Roman numeral corresponding with that key after a slash so, for example, **V/V** indicates the dominant chord of the dominant key of the present home-key. The dominant key of **C** major is **G** major so this secondary dominant is the chord of the fifth degree of the **G** major scale, which is **D** major. If used, this chord causes a modulation.

Chapter 23

Scale (music)

For psychoacoustic scale, see bark scale and mel scale.

In music, a **scale** is any set of musical notes ordered

Ascending and descending chromatic scale Play

Pattern of intervals in the C-major scale Play

by fundamental frequency or pitch. A scale ordered by increasing pitch is an ascending scale, while descending scales are ordered by decreasing pitch. Some scales contain different pitches when ascending than when descending (for instance, see Melodic minor scale).

Often, especially in the context of the common practice period, part or all of a musical work including melody and/or harmony, is built using the notes of a single scale, which can be conveniently represented on a staff with a standard key signature.[1]

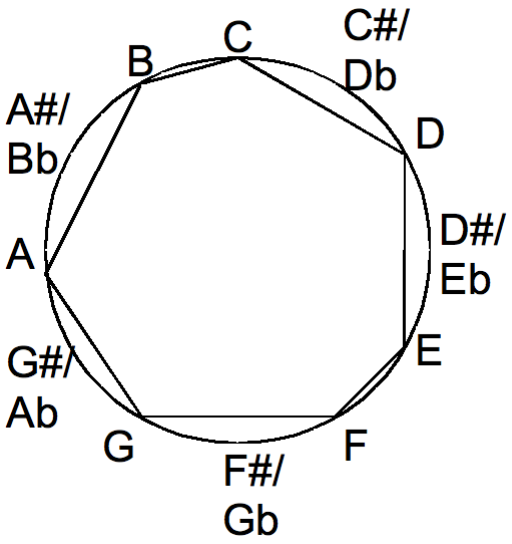
Due to the principle of octave equivalence, scales are generally considered to span a single octave, with higher or lower octaves simply repeating the pattern. A musical scale represents a division of the octave space into a certain number of scale steps, a scale step being the recognizable distance (or interval) between two successive notes of the scale.[2]

A measure of the width of each scale step provides a method to classify scales. For instance, in a chromatic scale each scale step represents a semitone interval, while a major scale is defined by the interval pattern T–T–S–T–T–T–S, where T stands for whole tone (an interval spanning two semitones), and S stands for semitone. Based on their interval patterns, scales are divided into categories including diatonic, chromatic, major, minor, and others.

A specific scale is defined by its characteristic interval pattern and by a special note, known as its first degree (or tonic). The tonic of a scale is the note selected as the beginning of the octave, and therefore as the beginning of the adopted interval pattern. Typically, the name of the scale specifies both its tonic and its interval pattern. For example, C-major indicates a major scale in which C is the tonic.

23.1 Background

23.1.1 Scales, steps, and intervals



Diatonic scale in the chromatic circle

Scales are typically listed from low to high. Most scales are *octave-repeating*, meaning their pattern of notes is the same in every octave (the Bohlen–Pierce scale is one exception). An octave-repeating scale can be represented as a circular arrangement of pitch classes, ordered by increasing (or decreasing) pitch class. For instance, the increasing C major scale is C–D–E–F–G–A–B–[C], with the bracket indicating that the last note is an octave higher than the first note, and the decreasing C major scale is C–B–A–G–F–E–D–[C], with the bracket indicating an octave lower than the first note in the scale.

The distance between two successive notes in a scale is called a scale step.

The notes of a scale are numbered by their steps from the root of the scale. For example, in a C major scale the first note is C, the second D, the third E and so on. Two notes can also be numbered in relation to each other: C and E create an interval of a third (in this case a major third); D and F also create a third (in this case a minor third).

23.1.2 Scales and pitch

A single scale can be manifested at many different pitch levels. For example, a C major scale can be started at C4 (middle C; see scientific pitch notation) and ascending an octave to C5; or it could be started at C6, ascending an octave to C7. As long as all the notes can be played, the octave they take on can be altered.

23.1.3 Types of scale

Scales may be described according to the intervals they contain:

- for example: diatonic, chromatic, whole tone

or by the number of different pitch classes they contain:

- Octatonic (8 notes per octave): used in jazz and modern classical music
- Heptatonic (7 notes per octave): the most common modern Western scale
- Hexatonic (6 notes per octave): common in Western folk music
- Pentatonic (5 notes per octave): common in folk music, especially in oriental music; also known as the "black note" scale
- Tetratonic (4 notes), tritonic (3 notes), and ditonic (2 notes): generally limited to prehistoric ("primitive") music
- Monotonic (1 note): limited use in liturgy, and for effect in modern art music

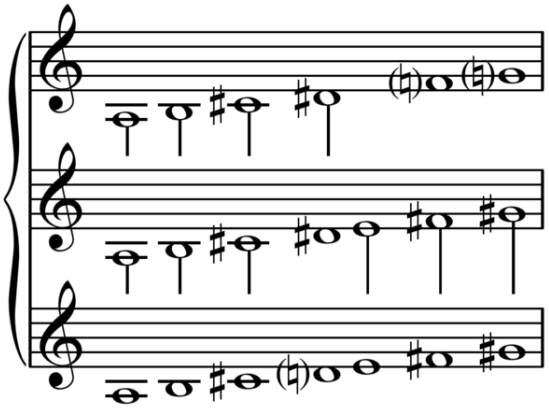
"The number of the notes that make up a scale as well as the quality of the intervals between successive notes of the scale help to give the music of a culture area its peculiar sound quality."[3] "The pitch distances or intervals among the notes of a scale tell us more about the sound of the music than does the mere number of tones."[4]

23.1.4 Harmonic content

The notes of a scale form intervals with each of the other notes of the chord in combination. A 5-note scale has 10 of these harmonic intervals, a 6-note scale has 15, a 7-note scale has 21, an 8-note chord has 28.[5] Though the scale is not a chord, and might never be heard more than one note at a time, still the absence, presence, and placement of certain key intervals plays a large part in the sound of the scale, the natural movement of melody within the scale, and the selection of chords taken naturally from the scale.[6]

A musical scale containing tritones is called tritonic; one without tritones is atritonic. A scale or chord containing semitones is called hemitonic; one without semitones is anhemitonic. The significance of these categories lies in their bases of semitones and tritones being the severest of dissonances, avoidance of which is often desirable. The most used scales across the planet are anhemitonic.

23.1.5 Scales in composition



The lydian mode Play , middle, functions as an intermediary between the whole tone scale Play , top, and the major scale Play , bottom.

Scales can be abstracted from performance or composition. They are also often used precompositionally to guide or limit a composition. Explicit instruction in scales has been part of compositional training for many centuries. One or more scales may be used in a composition, such as in Claude Debussy's *L'Isle Joyeuse*.[7] To the right, the first scale is a whole tone scale, while the second and third scales are diatonic scales. All three are used in the opening pages of Debussy's piece.

23.2 Western music

See also: Musical mode

Scales in traditional Western music generally consist of seven notes and repeat at the octave. Notes in the commonly used scales (see just below) are separated by whole and half step intervals of *tones* and *semitones*. The har-

monic minor scale includes a three-semitone step; the pentatonic includes two of these.

Western music in the Medieval and Renaissance periods (1100–1600) tends to use the white-note diatonic scale C–D–E–F–G–A–B. Accidentals are rare, and somewhat unsystematically used, often to avoid the tritone.

Music of the common practice periods (1600–1900) uses three types of scale:

- The diatonic scale (seven notes)—this includes the major scale and the natural minor
- The melodic and harmonic minor scales (seven notes)

These scales are used in all of their transpositions. The music of this period introduces *modulation,* which involves systematic changes from one scale to another. Modulation occurs in relatively conventionalized ways. For example, major-mode pieces typically begin in a "tonic" diatonic scale and modulate to the "dominant" scale a fifth above.

In the 19th century (to a certain extent), but more in the 20th century, additional types of scales were explored:

- The chromatic scale (twelve notes)
- The whole tone scale (six notes)
- The pentatonic scale (five notes)
- The octatonic or diminished scales (eight notes)

A large variety of other scales exists, some of the more common being:

- The Phrygian dominant scales (actually, a mode of the harmonic minor scale)
- The Arabic scales
- The Hungarian minor scale
- The Byzantine Music scales (called echoi)
- The Persian scale

Scales such as the pentatonic scale may be considered *gapped* relative to the diatonic scale. An *auxiliary scale* is a scale other than the primary or original scale. See: modulation (music) and Auxiliary diminished scale.

23.3 Naming the notes of a scale

In many musical circumstances, a specific note of the scale will be chosen as the tonic—the central and most stable note of the scale, also known as the root note. Relative to a choice of tonic, the notes of a scale are often labeled with numbers recording how many scale steps above the tonic they are. For example, the notes of the C major scale (C, D, E, F, G, A, B) can be labeled {1, 2, 3, 4, 5, 6, 7}, reflecting the choice of C as tonic. The expression scale degree refers to these numerical labels. Such labeling requires the choice of a "first" note; hence scale-degree labels are not intrinsic to the scale itself, but rather to its modes. For example, if we choose A as tonic, then we can label the notes of the C major scale using A = 1, B = 2, C = 3, and so on. When we do so, we create a new scale called the A minor scale. See the Note article for how the notes are customarily named in different countries.

The scale degrees of a heptatonic (7-note) scale can also be named using the terms tonic, supertonic, mediant, subdominant, dominant, submediant, subtonic. If the subtonic is a semitone away from the tonic, then it is usually called the leading-tone (or leading-note); otherwise the leading-tone refers to the raised subtonic. Also commonly used is the (movable do) solfège naming convention in which each scale degree is denoted by a syllable. In the major scale, the solfege syllables are: Do, Re, Mi, Fa, So (or Sol), La, Ti (or Si), Do (or Ut).

In naming the notes of a scale, it is customary that each scale degree be assigned its own letter name: for example, the A major scale is written A–B–C♯–D–E–F♯–G♯ rather than A–B–D♭–D–E–E𝄪–G♯. However, it is impossible to do this with scales containing more than seven notes.

Scales may also be identified by using a binary system of twelve zeros or ones to represent each of the twelve notes of a chromatic scale. It is assumed that the scale is tuned using 12-tone equal temperament (so that, for instance, C♯ is the same as D♭), and that the tonic is in the leftmost position. For example the binary number 101011010101, equivalent to the decimal number 2773, would represent any major scale (such as C–D–E–F–G–A–B). This system includes scales from 100000000000 (2048) to 111111111111 (4095), providing a total of 2048 possible species, but only 352 unique scales containing from 1 to 12 notes.[8]

Scales may also be shown as semitones (or fret positions) from the tonic. For instance, 0 2 4 5 7 9 11 denotes any major scale such as C–D–E–F–G–A–B, in which the first degree is, obviously, 0 semitones from the tonic (and therefore coincides with it), the second is 2 semitones from the tonic, the third is 4 semitones from the tonic, and so on. Again, this implies that the notes are drawn from a chromatic scale tuned with 12-tone equal temperament.

23.4 Scalar transposition

Composers often transform musical patterns by moving every note in the pattern by a constant number of scale steps: thus, in the C major scale, the pattern C–D–E might be shifted up, or transposed, a single scale step to become D–E–F. This process is called "scalar transposition" and can often be found in musical sequences. Since the steps of a scale can have various sizes, this process introduces subtle melodic and harmonic variation into the music. This variation is what gives scalar music much of its complexity.

23.5 Jazz and blues

See also: Jazz scales

Through the introduction of blue notes, jazz and blues employ scale intervals smaller than a semitone. The blue note is an interval that is technically neither major nor minor but "in the middle", giving it a characteristic flavour. For instance, in the key of E, the blue note would be either a note between G and G♯ or a note moving between both. In blues a pentatonic scale is often used. In jazz many different modes and scales are used, often within the same piece of music. Chromatic scales are common, especially in modern jazz.

23.6 Non-Western scales

In Western music, scale notes are often separated by equally tempered tones or semitones, creating 12 notes per octave. Many other musical traditions use scales that include other intervals or a different number of pitches. These scales originate within the derivation of the harmonic series. Musical intervals are complementary values of the harmonic overtones series.[9] Many musical scales in the world are based on this system, except most of the musical scales from Indonesia and the Indochina Peninsulae, which are based on inharmonic resonance of the dominant metalophone and xylophone instruments. A common scale in Eastern music is the pentatonic scale, consisting of five notes. In the Middle Eastern Hejaz scale, there are some intervals of three semitones. Gamelan music uses a small variety of scales including Pélog and Sléndro, none including equally tempered nor harmonic intervals. Indian classical music uses a moveable seven-note scale. Indian Rāgas often use intervals smaller than a semitone.[10] Arabic music maqamat may use quarter tone intervals.[11] In both rāgas and maqamat, the distance between a note and an inflection (e.g., śruti) of that same note may be less than a semitone.

23.7 Microtonal scales

The term *microtonal music* usually refers to music with roots in traditional Western music that uses non-standard scales or scale intervals. Mexican composer Julián Carrillo created in the late 19th century microtonal scales which he called "Sonido 13", The composer Harry Partch made custom musical instruments to play compositions that employed a 43-note scale system, and the American jazz vibraphonist Emil Richards experimented with such scales in his Microtonal Blues Band in the 1970s. Easley Blackwood has written compositions in all equal-tempered scales from 13 to 24 notes. Erv Wilson introduced concepts such as Combination Product Sets (Hexany), Moments of Symmetry and golden horagrams, used by many modern composers. Microtonal scales are also used in traditional Indian Raga music, which has a variety of modes which are used not only as modes or scales but also as defining elements of the song, or raga.

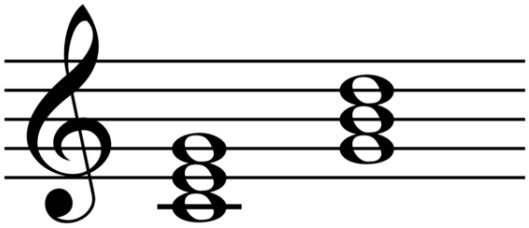
Chapter 24

Dominant (music)

For the term "dominant function" on the Myers-Briggs Type Indicator, see Myers-Briggs Type Indicator#Dominant function.

In music, the **dominant** is the fifth scale degree of the



Tonic and dominant in C Play . C major and G major chords.

The second to last chord in this example is built on the dominant (V) and found here in the circle progression on C: I-IV-vii°-iii-vi-ii-V-I Play

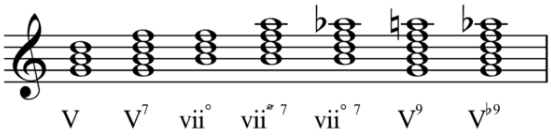
diatonic scale, called "dominant" because it is next in importance to the tonic,[1] and a **dominant chord** is any chord built upon that pitch, using the notes of the same diatonic scale. The **dominant function** (diatonic function) has the role of creating instability that requires the tonic for resolution.

> In very much conventionally tonal music, harmonic analysis will reveal a broad prevalence of the primary (often triadic) harmonies: tonic, dominant, and subdominant (i.e., I and its chief auxiliaries a 5th removed), and especially the first two of these.
> —Berry (1976)[2]

> The scheme I-x-V-I symbolizes, though naturally in a very summarizing way, the harmonic course of any composition of the Classical period. This *x*, usually appearing as a progression of chords, as a whole series, constitutes, as it were, the actual "music" within the scheme, which through the annexed formula V-I, is made into a unit, a group, or even a whole piece.
> —Rudolph Reti, (1962)[3] quoted in[4]

For example, in the C major scale (white keys on a piano, starting with C), the dominant is the note G; and the dominant triad consists of the notes G, B, and D.

24.1 Dominant chords



Chords with a dominant function: dominant (seventh, ninth, and flat ninth) and leading-tone (diminished, half-diminished seventh, and diminished seventh).[5] Play

24.1.1 Triads

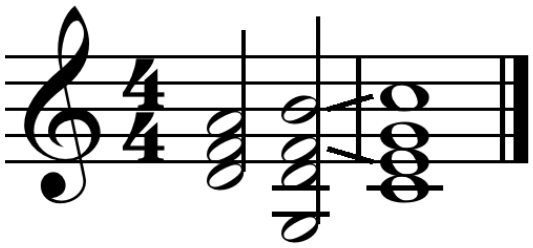
In music theory, the dominant triad (3-note chord) is a major triad, symbolized by the Roman numeral V, if it is within the major diatonic scale (for example G-B-D in C major). It is, however, a minor triad, denoted v, if it is within the minor diatonic scale (for example G-B♭-D in C minor). In the minor scale, the dominant triad is often substituted with a major triad, by sharpening the second note, which is a minor third from the dominant note, into

a major third, since the major third from the dominant is the leading tone for the minor scale. For instance, in G-B♭-D, the B♭ is sharpened to B natural (B♮), since B♮ is the leading tone for the C minor scale. See: harmonic minor scale.

24.1.2 Seventh chord

A dominant seventh chord is a chord built upon the dominant of a major diatonic scale. It contains a major triad and a minor seventh of the root of the triad. An example is G^7 in C major: G-B-D-F, with G being both the dominant of C major and the root of the major triad G-B-D, and F being the minor seventh of the root. In a general context, the dominant seventh is denoted V^7.

As defined by the 19th century musicologist Joseph Fétis the *dominante* was a seventh chord over the first note of a descending perfect fifth in the *basse fondamentale* or root progression, the common practice period dominant seventh he named the *dominante tonique*.[6]



Dominant chord (V) in the ii-V-I cadence on C Play

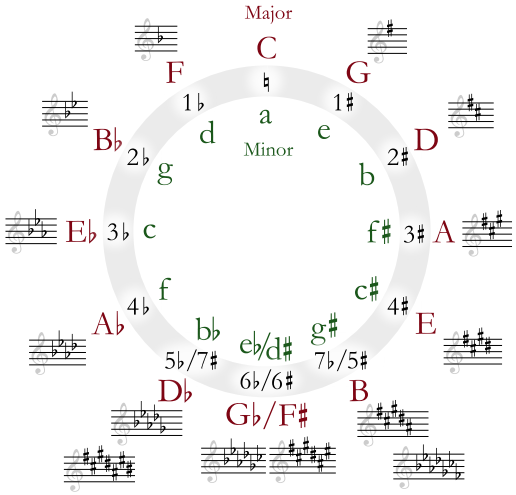
24.1.3 Dominant chord in authentic cadence

A cadential dominant chord followed by a tonic chord (the chord of the key of the piece) is denominated as authentic cadence. If the roots are in the bass and the tonic is in the highest voice, it is called a perfect authentic cadence.

24.2 Dominant key

The **dominant key** in a given musical composition is the key whose tonic is a perfect fifth above (or a perfect fourth below) the tonic of the main key of the piece. Put another way, the key whose tonic is the dominant scale degree in the main key.[7]

If, for example, a piece is written in the key of C major, then the key of C is the tonic key. The key of G major is the dominant key since it is based on the dominant note for the key of C major.[8] With a key signature of one sharp, G major features one more sharp than C major.



The key immediately clockwise is the dominant key of the key immediately counterclockwise, and features either one more sharp or one less flat.

In sonata form in major keys, the second subject group is usually in the dominant key. Even with the widest roaming modulations in the development, the dominant key exerts influence and eventually forces a return to the tonic key. [9]

24.2.1 In tonal modulation

Modulation to the dominant in Haydn's Symphony in C Major, No. 97 (reduction). Play

> The movement to the dominant was part of musical grammar, not an element of form. Almost all music in the eighteenth century went to the dominant: before 1750 it was not something to be emphasized; afterward, it was something that the composer could take advantage of. This means that every eighteenth century listener expected the movement to the dominant in the sense that [one] would have been puzzled if [one] did not get it; it was a necessary condition of intelligibility.
> —Charles Rosen (1972)[10]

"Dominant" also refers to a relationship of musical keys. For example, relative to the key of C major, the key of G major is the dominant key. Music which modulates (changes key) often modulates into the dominant.

Modulation into the dominant key often creates a sense of increased tension; as opposed to modulation into subdominant (fourth note of the scale), which creates a sense of musical relaxation.

> The vast majority of harmonies designated as "essential" in the basic frame of structure must be I and V–the latter, *when tonal music is viewed in broadest terms*, an auxiliary support and embellishment of the former, for which it is the principal medium of tonicization.
> —Berry (1976)[2]

The dominant chord itself is composed of the dominant (sol), the leading-tone (ti), and the supertonic (re) scale degrees. According to the rules of tonal resolution, both the leading-tone and the supertonic primarily resolve to the tonic. These two tones resolving to the tonic are strengthened by the dominant scale degree, which is a common tone between the tonic and dominant chords. The dominant may also be considered the result of a transformational operation applied to the tonic that most closely resembles the tonic by some clear-cut criteria such as common tones.[11]

24.3 In non-Western music

The dominant is an important concept in Middle Eastern music. In the Persian Dastgah, Arabic maqam and the Turkish makam, scales are made up of trichords, tetrachords and pentachords (each called a *jins* in Arabic), with the tonic of a maqam being the lowest note of the lower jins and the dominant being that of the upper jins. The dominant of a maqam is not always the fifth, however; for example, in Kurd and Bayati, the dominant is the fourth, and in maqam Saba, the dominant is the minor third. A maqam may have more than one dominant.

Chapter 25

Sequence (music)

For the unrelated genre of Gregorian chant, see Sequence (poetry). For the means of triggering musical notes, see Music sequencer.

Sequence ascending by step Play . Note that there are only four segments, continuingly higher, and that the segments continue by similar distance (seconds: C-D, D-E, etc.).

Real, rather than tonal, sequence. Play

In music, a **sequence** is the immediate restatement of a motif or longer melodic (or harmonic) passage at a higher or lower pitch in the same voice.[1] It is one of the most common and simple methods of elaborating a melody in eighteenth and nineteenth century classical music[1] (Classical period and Romantic music). Characteristics of sequences:[1]

- Two segments, usually no more than three or four
- Usually only one direction: continuingly higher or lower
- Segments continue by same interval distance

It is possible for melody or harmony to form a sequence without the other participating.

A **real sequence** is a sequence where the subsequent segments are exact transpositions of the first segment. A **tonal sequence** is a sequence where the subsequent segments are diatonic transpositions of the first segments. A **modified sequence** is a sequence where the subsequent segments are decorated or embellished so as to not destroy the character of the original segment. A **false sequence** is a literal repetition of the beginning of a figure and stating the rest in sequence.[1] A **modulating sequence** is a sequence that leads from one tonal center to the next, with each segment technically being in a different key in some sequences.[2] A **rhythmic sequence** is the repetition of a rhythm with free use of pitches.

A sequence can be described according to its direction (ascending or descending in pitch) and its adherence to the diatonic scale—that is, the sequence is diatonic if the pitches remain within the scale, or chromatic (or non-diatonic) if pitches outside of the diatonic scale are used and especially if all pitches are shifted by exactly the same interval (i.e., they are transposed). The non-diatonic sequence tends to modulate to a new tonality or to cause temporarily tonicisation.

At least two instances of a sequential pattern—including the original statement—are required to identify a sequence, and the pattern should be based on several melody notes or at least two successive harmonies (chords). Although stereotypically associated with Baroque music, and especially the music of Antonio Vivaldi, this device is widespread throughout Western music history.

> The device of sequence epitomises both the goal-directed and the hierarchical nature of common-practice tonality. It is particularly prevalent in passages involving extension or elaboration; indeed, because of its inherently directed nature, it was (and still is) often pulled from the shelf by the less imaginative tonal composer as the stock response to a need for transitional or developmental activity. Whether dull or masterly, however, the emphasis is on the underlying process rather than the material itself.
> —Christopher Mark (2006), [3]

Ritornellos and the amplification from melodies to Baroque lyrics are often built from sequences.[4]

25.1 Types of sequences

There are many types of sequences, each with a unique pattern. Listed below are some examples.

25.1.1 Descending fifths

Descending fifths sequences, also known as "circle of fifths" sequences, are the most commonly used types of sequences,[5] singular extended in some works of Claudio Monteverdi and Heinrich Schütz.[6] It usually consists of a series of chords whose bass or "root" notes follow a pattern of descending fifths (or ascending fourths).

For example, if a descending fifths sequence in C major starts with the note C, the next note will be F, a perfect fifth below the first note. The next few notes will be B, E, A, D and so on, following a pattern of descending fifths.[7]

A descending fifths sequence in C major. Notice the "circle of fifths" pattern in the lower staff. Play

25.1.2 Ascending fifths

The ascending fifths sequence, contrary to the descending fifths sequence, consists of a pattern of ascending fifths (or descending fourths). It is much less common than the descending fifths sequence.[5]

An ascending fifths sequence in C major. Notice the "circle of fifths" pattern in the lower staff similar to the descending fifths sequence, except going in the opposite direction. Play

25.1.3 Descending thirds

A descending thirds sequence consists of a series of chords whose root notes descend by a third each time. Sometimes, notes are added in-between these root notes in order to create a smoother bass line.[5]

A descending thirds sequence in C major. The pattern in the lower staff descends by a third each time in this sequence. Play

25.1.4 Pachelbel sequence

The Pachelbel sequence is very common, and is named after Johann Pachelbel, who used it in Pachelbel's Canon. It consists of a pattern of alternating between descending a fourth and ascending a second. In other words, the pattern first skips down a fourth, then up a second, down a fourth, and so on. For example, if a Pachelbel sequence in C major starts on C, the next note will be G, followed by A, E, F, etc.[7]

Play

Another version of the Pachelbel sequence is to make every other chord in first inversion. This makes a continuous bass line, which is very convenient when writing a chord progression. Consider the chord sequence: C, G, A, E. Putting every other chord in first inversion will render the chord sequence like so: C, G/B, A, E/G. This will create the bass line with the notes C, B, A, G, a descending scale.[7]

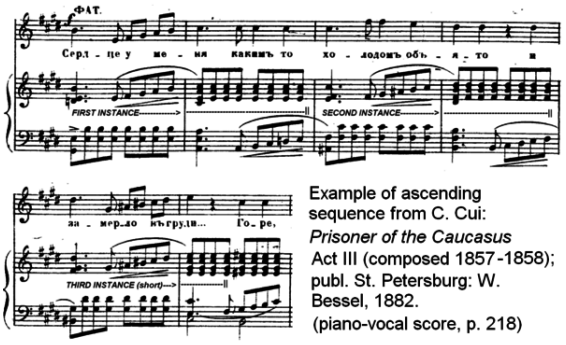
Play

25.2 Examples

Sequence in J.S. Bach's Fugue in G major BWV 860, mm. 17-19, also considered a bridge. Play

A well-known popular example of a threefold *descending* diatonic sequence is found in the refrain from the Christmas carol "Angels We Have Heard on High,"[4] as illustrated immediately below ("Glo...ria in excelsis Deo"). The one-measure melodic motive is shifted downward at the interval of a second, and the harmonic aspect does so likewise by following the circle of fifths Play :

The following three-fold *ascending* chromatic (non-diatonic) sequence occurs in the duet of Abubeker and Fatima from Act III of César Cui's opera *Prisoner of the Caucasus* (compare a similar passage in the famous Rodgers and Hammerstein song "Do-Re-Mi," composed almost exactly 100 years later) Play :



Example of ascending sequence from C. Cui: *Prisoner of the Caucasus* Act III (composed 1857-1858); publ. St. Petersburg: W. Bessel, 1882. (piano-vocal score, p. 218)

Handel's "For Unto Us a Child is Born" (HWV 56) relies heavily on both melodic and harmonic sequencing, as can be seen in the following excerpt. In this vocal reduction, the soprano and alto lines reiterate a florid two-beat melodic motif for three and a half bars in a series of melodic sequences on the word "born." More subtle, though still present, are the underlying harmonic sequences. Play

Other examples include Handel's "Ev'ry valley shall be exalted" ("exalted") from *Messiah*, the opening unison ritornello of J.S. Bach's D-minor harpsichord concerto.[4] Another can be found in Arcangelo Corelli's sonata de camera gigue in Em. Here the composer sequences up in pitch after cadencing on a V.

Chapter 27

Diatonic and chromatic

"Chromatic" redirects here. For other uses, see Chromatic (disambiguation).

Diatonic (Greek: διατονική) and ***chromatic*** (Greek: χρωματική) are terms in music theory that are most often used to characterize scales, and are also applied to musical instruments, intervals, chords, notes, musical styles, and kinds of harmony. They are very often used as a pair, especially when applied to contrasting features of the common practice music of the period 1600–1900.[3]

Melodies may be based on a diatonic scale and maintain its tonal characteristics but contain many accidentals up to all twelve tones of the chromatic scale, such as the opening of Henry Purcell's "Thy Hand, Belinda", Dido and Aeneas (1689) (Play , Play with figured bass) which features eleven of twelve pitches while chromatically descending by half steps,[1] the missing pitch being sung later.

Béla Bartók - Music for Strings, Percussion and Celesta, *mov. I, fugue subject: chromatic Play .*[2]

Bartok - Music for Strings, Percussion and Celesta, *mov. I, fugue subject: diatonic variant Play .*[2]

These terms may mean different things in different contexts. Very often, ***diatonic*** refers to musical elements derived from the modes and transpositions of the "white note scale" C–D–E–F–G–A–B (see details below).[4] In some usages it includes all forms of heptatonic scale that are in common use in Western music (the major, and all forms of the minor).[5] ***Chromatic*** most often refers to structures derived from the chromatic scale, which consists of all semitones. Historically, however, it had other senses, referring in Ancient Greek music theory to a particular tuning of the tetrachord, and to a rhythmic notational convention in mensural music of the 14th through 16th centuries.

27.1 History

27.1.1 Greek genera

Main article: Tetrachord

In ancient Greece there were three standard tunings (known by the Latin word *genus*, plural *genera*)[6] of a lyre.[7] These three tunings were called *diatonic*,[8] *chromatic*,[9] and *enharmonic*,[10] and the sequences of four notes that they produced were called *tetrachords* ("four strings").[11] A diatonic tetrachord comprised, in descending order, two whole tones and a semitone, such as A G F E (roughly). In the chromatic tetrachord the second string of the lyre was lowered from G to G♭, so that the two lower intervals in the tetrachord were semitones, making the pitches A G♭ F E. In the enharmonic tetrachord the tuning had two quarter tone intervals at the bottom: A G𝄫 F♭ E (where F♭ is F♮ lowered by a quarter tone). For all three tetrachords, only the middle two strings varied in their pitch.[12]

27.1.2 Medieval coloration

The term **cromatico** (Italian) was occasionally used in the Medieval and Renaissance periods to refer to the *coloration* (Latin *coloratio*) of certain notes. The details vary widely by period and place, but generally the ad-

OF MUSIC. 261

the other three, they made the * *Tetrachord* complete; and it was the different manner in which harmony was produced by these four strings, that constituted the three kinds of it, called the *Diatonic*, *Chromatic*, and *Inharmonic*. The *Diatonic* kind appertains to the common and ordinary music. In the *Chromatic*, the music was softened by lowering the sounds half a tone, which was directed by a coloured mark, from whence the Chromatic took its name χρῶμα, signifying *colour*. What is now called B flat belongs to the Chromatic music. In the Inharmonic music, on the contrary, the sounds were raised a demi-tone, which was marked, as at present, by a diesis. In the *Diatonic* music, the air or tune could not make its progressions by less intervals than the semi-tones major. The modulation of the *Chromatic* music made use of the semi-tones minor. In the *Inharmonic* music, the progression of the air might be made by quarter-tones,

Lib. 2. in Somn. Scipion, c. 4.

Macrobius, speaking of these three kinds, says, the Inharmonic is no longer in use upon account of its difficulty; that the Chromatic is no longer esteemed, because that sort of music is too soft and effeminate; and that the Diatonic holds the mean between them both.

The addition of a fifth string produced the *Pentachord*. The lyre with seven strings, or the *Heptachord*, was more used, and in greater esteem than all others. However, though it included the seven notes of music, the octave was still wanting. Simonides at length added it, according to Pliny, with an eighth string. Long after him, Timotheus the Milesian, who lived in the reign of Philip king of Macedon, about the 108th olympiad,

dition of a colour (often red) to an empty or filled head of a note, or the "colouring in" of an otherwise empty head of a note, shortens the duration of the note.[13] In works of the Ars Nova from the 14th century, this was used to indicate a temporary change in metre from triple to duple, or vice versa. This usage became less common in the 15th century as open white noteheads became the standard notational form for minims (half-notes) and longer notes (see *white mensural notation*).[14][15] Similarly, in the 16th century, notation in a 4/4 time signature was referred to as "chromatic" notation because of its abundance of "coloured in" black notes, that is semiminims (crotchets or quarter notes) and shorter notes, as opposed to the open white notes of the more common 2/2 metre.[16] These uses for the word have no relationship to the modern meaning of *chromatic*, but the sense survives in the current term *coloratura*.[17]

27.1.3 Renaissance chromaticism

See also: Chromaticism

The term *chromatic* began to approach its modern usage in the 16th century. For instance Orlando Lasso's *Prophetiae Sibyllarum* opens with a prologue proclaiming, "these chromatic songs,[18] heard in modulation, are those in which the mysteries of the Sibyls are sung, intrepidly," which here takes its modern meaning referring to the frequent change of key and use of chromatic intervals in the work. (The *Prophetiae* belonged to an experimental musical movement of the time, called musica reservata). This usage comes from a renewed interest in the Greek genera, especially its chromatic tetrachord, notably by the influential theorist Nicola Vicentino in his treatise on ancient and modern practice, 1555.[19]

27.2 Diatonic scales

Diatonic scale on C Play equal tempered and Play just.

Main article: Diatonic scale

Medieval theorists defined scales in terms of the Greek

GAMMUT } "Γαμμα: becauſe Guy of Arezzo,
GAMUT } a Benedictine monk, who reformed the church muſic, about the year 1024, compoſed a muſical ſcale with theſe ſix words, *ut, re, mi, fa, ſol, la*; by which means, he ſays, muſic becomes eaſier to learn in ſix days than it was before in ſix months: afterwards he placed on the ſide of theſe notes, the following ſeven letters, *a, b, c, d, e, f, g*; and, by reaſon that he placed the letter *g* on the note which he had added to his antient ſyſtem, the whole ſcale was therefore denominated, as it is to this very day, *gammut*: but if, with *Aretinus*'s gammut, muſic could be learnt in ſix days, it may be ſafely ſaid, that we can now learn it with greater eaſe *in ſix hours*, through the help of the invention ſince made of a ſeventh note; which frees us of all the trouble and embarraſſment of the diviſions: Nug."—the Dr. is the moſt expeditious maſter of muſic I ever heard of, to teach it *with greater eaſe in ſix hours!*—Clel. Voc. 14, n, ſays, " in fact, moſt, if not all the antient *gemotts*, or *popular aſſemblies*, were attended with various *ſports*; thence *ſport* was metonimically called *gemott*; whence that vulgariſm *gamut*, which, however, is the true origin of the word now in uſe; and, by contraction, *game*:"—but if this be the true origin, it is Gr.: ſee MEETING. Gr.

Gamut *as defined by George William Lemon,* English Etymology, *1783.*

tetrachords. The *gamut* was the series of pitches from which all the Medieval "scales" (or modes, strictly) are notionally derived, and it may be thought of as constructed in a certain way from diatonic tetrachords. The

origin of the word *gamut* is explained at the article Hexachord; here the word is used in one of the available senses: the all-encompassing gamut as described by Guido d'Arezzo (which includes all of the modes).

The intervals from one note to the next in this Medieval gamut are all tones or semitones, recurring in a certain pattern with five tones (T) and two semitones (S) in any given octave. The semitones are separated as much as they can be, between alternating groups of three tones and two tones. Here are the intervals for a string of ascending notes (starting with F) from the gamut:

... –T–T–T–S–T–T–S–T–T–T–S–T– ...

And here are the intervals for an ascending octave (the seven intervals separating the eight notes A–B–C–D–E–F–G–A) from the gamut:

T–S–T–T–S–T–T [five tones and two semitones][20]

In its most strict definition, therefore, a diatonic scale is one that may be derived from the pitches represented in successive white keys of the piano (or a transposition thereof): the modern equivalent of the gamut. (For simplicity, throughout this article equal temperament tuning is assumed unless otherwise noted.) This would include the major scale, and the natural minor scale (same as the descending form of the melodic minor), but not the old ecclesiastical church modes, most of which included both versions of the "variable" note B♮/B♭.

27.2.1 Modern meanings

There are specific applications in the music of the Common Practice Period, and later music that shares its core features.

All writers accept the major scale as diatonic. Most, but not all,[21] accept the natural minor as diatonic. As for other forms of the minor:

- "Exclusive" usage

  Some writers consistently classify the other variants of the minor scale – the melodic minor (ascending form) and the harmonic minor – as *non*-diatonic, since they are not transpositions of the white-note pitches of the piano. Among such theorists there is no agreed general term that encompasses the major and all forms of the minor scale.[22]

- "Inclusive" usage

  Some writers consistently include the melodic and harmonic minor scales as diatonic also. For this group, every scale standardly used in common practice music and much similar later music is either *diatonic* (the major, and *all* forms[23] of the minor) or *chromatic*.[24]

- "Mixed" usage

  Still other writers mix these two meanings of *diatonic* (and conversely for *chromatic*), and this may lead to confusions and misconceptions. Sometimes, though not always, the context makes it clear which meaning is intended.

For print sources employing each of these usages (for scales, and derived usages for intervals, etc.), see the list of sources, below.[25]

There are a few other meanings of the term *diatonic scale*, some of which take the extension to harmonic and melodic minor even further, to be even more inclusive.[26]

In general, *diatonic* is most often used inclusively with respect to music that restricts itself to standard uses of traditional major and minor scales. When discussing music that uses a larger variety of scales and modes (including much jazz, rock, and some tonal 20th-century concert music), writers often adopt the exclusive use to prevent confusion.

27.3 Chromatic scale

Main article: Chromatic scale

A **chromatic** scale consists of an ascending or descending sequence of pitches proceeding always by semitones. Such a sequence of pitches would, for example, be produced by playing black and white keys of a piano in order, without leaving any out. The structure of a chromatic scale is therefore uniform throughout, unlike major and minor scales which have tones and semitones in particular arrangements (and an augmented second, in the harmonic minor).[27]

Chromatic scale on C: full octave ascending and descending Play

.

27.4 Musical instruments

Some instruments, such as the violin, can be played in any scale; others, such as the glockenspiel, are restricted to the scale to which they are tuned. Among this latter class, some instruments, such as the piano, are always tuned to a chromatic scale, and can be played in any key, while others are restricted to a diatonic scale, and therefore to a

particular key. Some instruments, such as the harmonica, harp, and glockenspiel, are available in both diatonic and chromatic versions.

27.5 Intervals

The *diatonic intervals* are usually understood as those between some pair of notes both drawn from the same diatonic scale. Intervals that cannot be so derived are then called *chromatic intervals*. Because *diatonic scale* is itself ambiguous, this way of distinguishing intervals is also ambiguous.[28] For example, the interval B♮–E♭ (a diminished fourth, occurring in C harmonic minor) is considered diatonic if the harmonic minor scale is considered diatonic;[29] but it is considered chromatic if the harmonic minor scale is *not* considered diatonic.[30]

Additionally, the label *chromatic* or *diatonic* for an interval may be sensitive to context. For instance, in a passage in C major, the interval C–E♭ could be considered a *chromatic* interval because it does not appear in the prevailing diatonic key; conversely in C minor it would be *diatonic*. This usage is still subject to the categorization of scales as above, e.g. in the B♮–E♭ example above, classification would still depend on whether the harmonic minor scale is considered diatonic.

27.5.1 In different systems of tuning

Pythagorean diatonic and chromatic interval: E♮-F♮ and E♮-E♯ Play .

In equal temperament, there is no difference in tuning (and therefore in sound) between intervals that are enharmonically equivalent. For example, the notes F and E♯ represent exactly the same pitch, so the diatonic interval C–F (a perfect fourth) sounds exactly the same as its enharmonic equivalent—the chromatic interval C–E♯ (an augmented third).

In systems other than equal temperament, however, there is often a difference in tuning between intervals that are enharmonically equivalent. In tuning systems that are based on a cycle of fifths, such as Pythagorean tuning and meantone temperament, these alternatives are labelled as *diatonic* or *chromatic* intervals. Under these systems the cycle of fifths is not circular in the sense that a pitch at one end of the cycle (e.g., G♯) is not tuned the same as the enharmonic equivalent at its other end (A♭); they are different by an amount known as a *comma*.

This broken cycle causes intervals that cross the break to be written as augmented or diminished *chromatic* intervals. In meantone temperament, for instance, chromatic semitones (E–E♯) are smaller than diatonic semitones (E–F),[31] and with consonant intervals such as the major third the enharmonic equivalent is generally less consonant.

The exception to this classification is the tritone, of which both enharmonic forms (e.g., C–F♯ and C–G♭) are equally distant along the cycle of fifths, making them inversions of each other at the octave. Because of this the ambiguity cannot be resolved where octave equivalence is assumed, and the label *diatonic* or *chromatic* for either form of tritone is not useful in the context of tuning (the choice is arbitrary, and therefore unspecific).

If the tritone is assumed diatonic, the classification of written intervals by this definition is not significantly different from the "drawn from the same diatonic scale" definition given above as long as the harmonic minor and ascending melodic minor scale variants are not included. Aside from tritones, all intervals that are either augmented or diminished are chromatic, and the rest are diatonic.

27.6 Chords

Diatonic chords are generally understood as those that are built using only notes from the same diatonic scale; all other chords are considered *chromatic*. However, given the ambiguity of *diatonic scale*, this definition, too, is ambiguous. And for some theorists, chords are only ever diatonic in a relative sense: the augmented triad E♭–G–B♮ is diatonic "to" or "in" C minor.[32]

On this understanding, the diminished seventh chord built on the leading note is accepted as diatonic in minor keys.[33]

If the strictest understanding of the term *diatonic scale* is adhered to - whereby only transposed 'white note scales' are considered diatonic - even a major triad on the dominant scale degree in C minor (G–B♮–D) would be chromatic or altered in C minor.[34] Some writers use the phrase "diatonic to" as a synonym for "belonging to". Therefore a chord can be said to be diatonic if its notes *belong* to the underlying diatonic scale of the key.

27.7 Harmony

The words *diatonic* and *chromatic* are also applied inconsistently to harmony:

- Often musicians call *diatonic harmony* any kind of harmony inside the major–minor system of common practice. When diatonic harmony is understood in this sense, the supposed term *chromatic harmony*

means little, because chromatic chords are also used in that same system.

- At other times, especially in textbooks and syllabuses for musical composition or music theory, *diatonic harmony* means *harmony that uses only "diatonic chords"*.[35] According to this usage, *chromatic harmony* is then harmony that extends the available resources to include chromatic chords: the augmented sixth chords, the Neapolitan sixth, chromatic seventh chords, etc.[36]
- Since the word *harmony* can be used of single classes of chords (*dominant harmony*, *E minor harmony*, for example), *diatonic harmony* and *chromatic harmony* can be used in this distinct way also.[37]

However,

- Chromatic harmony may be defined as "the use of two successive chords which belong to two different keys and therefore contain tones represented by the same note symbols but with different accidentals".[38] Four basic techniques produce chromatic harmony under this definition: modal interchange, secondary dominants, melodic tension, and chromatic mediants.[38]

27.8 Miscellaneous usages

27.8.1 Notes

In modern usage, the meanings of the terms *diatonic note* and *chromatic note* vary according to the meaning of the term *diatonic scale*. Generally – not universally – a note is understood as diatonic in a context if it belongs to the diatonic scale that is used in that context; otherwise it is chromatic.

27.8.2 Inflection

The term *chromatic inflection* (alternatively spelt *inflexion*) is used in two senses:

- Alteration of a note that makes it (or the harmony that includes it) chromatic rather than diatonic.[39]
- Melodic movement between a diatonic note and a chromatically altered variant (from C to C♯ in G major, or vice versa, for example).[40]

27.8.3 Progression

The term *chromatic progression* is used in three senses:

- Movement between harmonies that are not elements of any common diatonic system (that is, not of the same diatonic scale: movement from D–F–A to D♯–F♯–A, for example).[41]
- The same as the second sense of *chromatic inflection*, above.[42]
- In musica ficta and similar contexts, a melodic fragment that includes a chromatic semitone, and therefore includes a *chromatic inflection* in the second sense, above.[43]

The term *diatonic progression* is used in two senses:

- Movement between harmonies that both belong to at least one shared diatonic system (from F–A–C to G–B–E, for example, since both occur in C major).[44]
- In musica ficta and similar contexts, a melodic fragment that does not include a chromatic semitone, even if two semitones occur contiguously, as in F♯–G–A♭.[43]

27.8.4 Modulation

- Diatonic modulation is modulation via a diatonic progression.[45]
- Chromatic modulation is modulation via a chromatic progression, in the first sense given above.[45]

27.8.5 Pentatonic scale

- One very common kind of pentatonic scale that draws its notes from the diatonic scale (in the *exclusive* sense, above) is sometimes called the *diatonic pentatonic scale*: C–D–E–G–A[–C], or some other modal arrangement of those notes.
- Other pentatonic scales (such as the pelog scales) may also be construed as reduced forms of a diatonic scale, but are not labelled *diatonic*.[46]

27.9 Modern extensions

Traditionally, and in all uses discussed above, the term *diatonic* has been confined to the domain of pitch, and in a fairly restricted way. The common idea in those uses is that a specific selection is made from an underlying superset of pitches. A particular subset of seven pitch classes is selected from a superset of twelve semitonally incrementing pitch classes, to yield a particular heptatonic scale. Exactly which heptatonic scales (and even which *modes* of those scales) should count as diatonic is unsettled, as shown above. But the broad selection principle itself is not disputed, at least as a theoretical convenience.

27.9.1 Extended pitch selections

The selection of pitch classes can be generalised to encompass formation of non-traditional scales from the underlying twelve chromatic pitch classes.[26] Or a larger set of underlying pitch classes may be used instead. For example, the octave may be divided into varying numbers of equally spaced pitch classes. The usual number is twelve, giving the conventional set used in Western music. But Paul Zweifel[47] uses a group-theoretic approach to analyse different sets, concluding especially that a set of twenty divisions of the octave is another viable option for retaining certain properties associated with the conventional "diatonic" selections from twelve pitch classes.

27.9.2 Rhythms

It is possible to generalise this selection principle even beyond the domain of pitch. The diatonic idea has been applied in analysis of some traditional African rhythms, for example. Some selection or other is made from an underlying superset of metrical beats, to produce a "diatonic" rhythmic "scale" embedded in an underlying metrical "matrix". Some of these selections are diatonic in a way similar to the traditional diatonic selections of pitch classes (that is, a selection of seven beats from a matrix of twelve beats – perhaps even in groupings that match the tone-and-semitone groupings of diatonic scales). But the principle may also be applied with even more generality (including even *any* selection from a matrix of beats of *any* size).[48]

[3] Often *diatonic* and *chromatic* are treated as mutually exclusive opposites, concerning common practice music. This article deals mainly with common practice music, and later music that shares the same core features (including the same particular use of tonality, harmonic and melodic idioms, and types of scales, chords, and intervals). Where other music is dealt with, this is specially noted.

[4] This definition encompasses the natural minor scale (and equivalently the descending melodic minor), the major scale, and the ecclesiastical modes.

[5] For inclusion of the harmonic minor and the ascending melodic minor see the section Modern meanings of "diatonic scale" in this article.

[6] Translating the term used by Greek theorists: γένος, *génos*; plural γένη, *génē*.

[7] It is unclear whether the lyre in question was itself a presumed four-stringed instrument ("τετράχορδον ὄργανον"), as some have suggested (see Peter Gorman, *Pythagoras, a Life* (London: Routledge & K. Paul, 1979), p. 162: "The fundamental instrument of early Greek music was the tetrachord or four-stringed lyre which was tuned in accordance with the main concordances; the tetrachord was also the foundation of Greek harmonic theory"). The number of strings on early lyres and similar instruments is a matter of much speculation (see Martin Litchfield West, *Ancient Greek music* (Oxford and New York: Oxford University Press, 1994), especially pp. 62–64). Many later instruments had seven or perhaps more strings, and in that case the tetrachord must be thought of as based on a selection of four adjacent strings.

[8] The English word *diatonic* is ultimately from the Greek διατονικός (*diatonikós*), itself from διάτονος (*diátonos*), which may mean (as OED claims) "through the tones" (taking τόνος, *tónos*, to mean *interval of a tone*), or perhaps *stretched out* (as recorded in Liddell and Scott's *Greek Lexicon*). See also Barsky (*Chromaticism*, Barsky, Vladimir, Routledge, 1996, p. 2): "There are two possible ways of translating the Greek term 'diatonic': (1) 'running through tones', i.e. through the whole tones; or (2) a 'tensed' tetrachord filled up with the widest intervals". The second interpretation would be justified by consideration of the pitches in the diatonic tetrachord, which are more equally distributed ("stretched out") than in the chromatic and enharmonic tetrachords, and are also the result of tighter stretching of the two variable strings. It is perhaps also sounder on linguistic morphological grounds. (See also *Merriam-Webster Online*.) A completely separate explanation of the origins of the term *diatonic* appeals to the generation of the diatonic scale from "two tones": "Because the musical scale is based entirely on octaves and fifths, that is, two notes, it is called the 'diatonic scale' " (Phillips, Stephen, "Pythagorean aspects of music", in *Music and Psyche*, Vol. 3, available also online). But this ignores the fact that it is the element *di-* that means "two", not the element *dia-*, which has "through" among its meanings (see Liddell and Scott). There is a Greek term δίτονος (*dítonos*), which is applied to an interval equivalent to two tones. It yields the English words *ditone* and *ditonic* (see Pythagorean comma), but it is quite distinct from διάτονος. Yet another derivation assumes the sense "through the tones" for διάτονος, but interprets *tone* as meaning *individual note* of the scale: "The word diatonic means 'through the tones' (i.e., through the tones of the key)" (Gehrkens, 1914, see below; see also the Prout citation, at the same location). This is not in accord with any accepted Greek meaning, and in Greek theory it would fail to exclude the other tetrachords. The fact that τόνος itself has at least four distinct meanings in Greek theory of music contributes to the uncertainty of the exact meaning and derivation of διατονικός, even among ancient writers. (See Solon Michaelides, *The Music of Ancient Greece: An Encyclopaedia* (London; Faber

and Faber, 1978), pp. 335–40: "Tonos". Τόνος may refer to a pitch, an interval, a "key" or register of the voice, or a mode.) For more information, especially concerning the various exact tunings of the diatonic tetrachord, see Diatonic genus.

[9] *Chromatic* is from Greek χρωματικός (*khrōmatikós*), itself from χρῶμα (*khrṓma*), which means *complexion*, hence *colour* – or, specifically as a musical term, "a modification of the simplest music" (Liddell and Scott's *Greek lexicon*). For more information, especially concerning the various exact tunings of the chromatic tetrachord, see Chromatic genus.

[10] Occasionally, as in the Rollin excerpt shown in this section, spelt *inharmonic*; but in OED this is only given as a distinct word with a distinct etymology ("Not harmonic; not in harmony; dissonant,..."). The motivation and sources of the Greek term ἐναρμονικός (*enarmonikós*) are little understood. But the two roots are ἐν (*en*: "in") and ἁρμονία (*harmonía*: "good placement of parts", "harmony", "a scale, mode, or τόνος [in one sense; see notes above]"). So in some way the term suggests harmoniousness or good disposition of parts, but not in the modern sense of *harmony*, which has to do with simultaneous sounds. (See Solon Michaelides, *The Music of Ancient Greece: An Encyclopaedia* (London: Faber and Faber, 1978); Liddell and Scott; etc.) For more information, especially concerning the various exact tunings of the enharmonic tetrachord, see Enharmonic genus.

[11] In practice *tetrachord* (τετράχορδον; *tetrákhordon*) also meant the instrument itself. And it could also mean the interval of a perfect fourth between the pitches of the fixed top and bottom strings; therefore the various tunings were called *divisions of the tetrachord* (see OED, "Tetrachord").

[12] For general and introductory coverage of Greek theory see *Tuning and Temperament, A Historical Survey*, Barbour, J. Murray, 2004 (reprint of 1972 edition), ISBN 0-486-43406-0. These meanings in Greek theory are the ultimate source of the meanings of the words today, but through a great deal of modification and confusion in Medieval times. It would therefore be a mistake to consider the Greek system and the subsequent Western systems (Medieval, Renaissance, or contemporary) as closely similar simply because of the use of similar terms: "... the categories of the diatonic, chromatic and enharmonic genera developed within the framework of monodic musical culture and have little in common with the corresponding categories of modern music theory" (*Chromaticism*, Barsky, Vladimir, Routledge, 1996, p. 2). There were several Greek systems, in any case. What is presented here is merely a simplification of theory that spans several centuries, from the time of Pythagoras (c. 580 BCE – c. 500 BCE), through Aristoxenus (c. 362 BCE – after 320 BCE), to such late theorists as Alypius of Alexandria (fl. 360 CE). Specifically, there are more versions of each of the three tetrachords than are described here.

[13] Details of the practice for certain periods: "The device that was both the simplest and the most stable and durable was that known as *coloratio*. In principle, any note or group of notes subjected to coloration or blackening was reduced to two-thirds of the value that it would have enjoyed in its pristine state. In respect of any note in mensural notation that was equal in duration to two of that next smaller in value, the coloration of three in succession caused each to undergo reduction to two-thirds of its erstwhile value, so creating a triplet [... .] In the case of any note that was equal in duration to three of that next smaller, the coloration of three together likewise effected a proportional reduction in the value of each to two-thirds, so reducing perfect value to imperfect and commonly creating the effect called hemiola [... .] On occasions coloured notes could appear singly to denote imperfect value, especially to inhibit unwanted perfection and alteration," Roger Bowers, "Proportional notation", 2. Coloration, *New Grove Dictionary of Music and Musicians*, second edition, edited by Stanley Sadie and John Tyrrell (London: Macmillan Publishers, 2001).

[16] Grout, Donald J, and Palisca, Claude, *A History of Western Music*, 6th ed., Norton, New York, 2001, pp. 188–190.

[17] "The root of the Italian term is that of 'colour', and it is probably related through its use of diminution (the little notes that 'rush' to the next long note, as Bernhard writes) to the mensural practice of coloration" (*New Grove*, "Coloratura").

[18] Rendered by many as *Carmina chromatico*, though this is incorrect Latin; the title is given as *Carmina chromatica* (which is plural of Latin *carmen chromaticum*) in *New Grove Online*. The entire passage is relevant to present points in this article:

New Grove Online, "Musica Ficta", I, ii

[19] Grout et al., 2001, p. 188.

[20] Some theorists derive such a scale from a certain series of pitches rising by six perfect fifths: F–C–G–D–A–E–B. These pitches are then rearranged by transposition to a single-octave scale: C–D–E–F–G–A–B[–C] (the standard C major scale, with the interval structure T–T–S–T–T–T[–S]). A few theorists call the original untransposed series itself a "scale". Percy Goetschius calls that series the "natural scale" (*The Theory and Practice of Tone-Relations*, Schirmer, 1931 edition, p. 3; see further citation below).

[21] Goetschius, as cited below, accepts only the major as diatonic.

[22] A very clear statement of the "exclusive" stance is given in the excerpt from "The leading tone in direct chromaticism: from Renaissance to Baroque", Clough, John, 1957, below. The excerpt acknowledges and analyses the difficulties with logic, naming, and taxonomy in that stance.

[23] A few exclude only the harmonic minor as diatonic, and accept the ascending melodic, because it comprises only tones and semitones, or because it has all of its parts analysable as tetrachords in some way or other.

[24] However, *beyond* analysis of common practice music, even these writers do not typically consider non-standard uses of some familiar scales to be "diatonic". For example, unusual modes of the melodic or harmonic minor scale, such as used in early works by Stravinsky, are almost never described as "diatonic".

[25] The first "exclusive" usage seems to be gaining greater currency. Certainly it is becoming close to standard in academic writing, as can be seen by querying online archives (such as JSTOR) for recent uses of the term *diatonic*. Equally certainly, the second "inclusive" meaning is still strongly represented in non-academic writing (as can be seen by online searches of practically oriented music texts at, for example, Amazon.com). Overall, considerable confusion remains; on the evidence presented in the list of sources, there are very many sources in the third category: *Diatonic used vaguely, inconsistently, or anomalously*.

[26] Gould, M. (2000). "Balzano and Zweifel: Another Look at Generalized Diatonic Scales". *Perspectives of New Music* **38** (2): 88–105. doi:10.2307/833660. JSTOR 833660. An explicit example of such an extended general use of *diatonic scale* and related terms:

> Throughout this paper, I use the terms "diatonic," "pentatonic" and "chromatic" in their generic senses, as follows:
>
> (a) A "diatonic" scale is a scale formed from two intervals of different sizes, such that groups of several adjacent instances of the larger interval are separated by single instances of the smaller interval.
>
> (b) A "pentatonic" scale is a scale formed from two intervals of different sizes, such that groups of several adjacent instances of the smaller interval are separated by single instances of the larger interval. Therefore a generic "pentatonic" can contain more than five tones.
>
> (c) "Chromatic" refers to the interval formed between adjacent pitch-classes of any equal-tempered scale.

See also #Extended pitch selections, in this article. See also an exceptional usage by Persichetti, in a note to #Diatonic_pentatonic_scale, below.

[27] It is not usual for *chromatic scale* to be used in any different sense from this. A rare exception is found in *Elements of Musical Composition*, Crotch, William, 1830. (See the quotation from this text, below. See also extensive analysis in the excerpt from "The leading tone in direct chromaticism: from Renaissance to Baroque", Clough, John, 1957, in the same subsection below.) Outside of music altogether, *chromatic scale* may refer to Von Luschan's chromatic scale.

[28] There are several other understandings of the terms *diatonic interval* and *chromatic interval*. There are theorists who define all augmented and diminished intervals as *chromatic*, even though some of these occur in scales that everyone accepts as diatonic. (For example, the diminished fifth formed by B and F, which occurs in C major.) There are even some writers who define all *minor* intervals as chromatic (Goetschius, Percy, *The Theory and Practice of Tone-Relations*, 1931, p. 6; Goetschius assesses all intervals as if the lower note were the tonic, and since for him only the major scale is diatonic, only the intervals formed above the tonic in the major are diatonic; see also, for example, Harrison, Mark, *Contemporary Music Theory – Level Two*, 1999, p. 5). Some theorists take the *diatonic interval* to be simply a measure of the number of "scale degrees" spanned by two notes (so that F♯–E♭ and F♮–E♮ represent the same "diatonic interval": a seventh); and they use the term *chromatic interval* to mean the number of semitones spanned by any two pitches (F♯ and E♭ are "at a chromatic interval of nine semitones"). Some theorists use the term *diatonic interval* to mean "an interval named on the assumption of the diatonic system of Western music" (so that all perfect, major, minor, augmented, diminished intervals are "diatonic intervals"). It is not clear what *chromatic interval* would mean, if anything, in parallel with this usage for *diatonic*. Some theorists use *chromatic interval* to mean simply *semitone*, as for example in the article Chromatic fourth. See also Williams, Peter F., *The Chromatic Fourth during Four Centuries of Music*, OUP, 1997. Something close to this usage may be found in print. For example, the term *chromatically*, as used in: "The trill rises chromatically by step above this harmonic uncertainty, forming a chromatic fourth, ..." (Robin Stowel, *Beethoven: Violin Concerto* (Cambridge Music Handbooks), Cambridge and New York: Cambridge University Press, 2005, p. 66). The term as used in the phrase *chromatic fourth* itself perhaps means just what it means in *chromatic scale*, but here applied to a melodic *interval* rather than a scale.

[29] See for example William Lovelock, *The Rudiments of Music*, 1971.

[30] See for example the citation from *Grove Music Online* ("Diatonic"), below.

[31] Helmholtz, Hermann, trans. Alexander Ellis, *On the Sensations of Tone*, Dover, New York, 1954, pp. 433–435 and 546–548. The two notes of a diatonic semitone have different letter-names; those of a chromatic semitone have the same letter-name.

[32] Kostka, Stefan, and Payne, Dorothy, *Tonal Harmony*, McGraw-Hill, 5th edition, 2003, pp. 60–61.

[33] "Because of the variability of [scale degrees] 6 and 7, there are sixteen possible diatonic seventh chords in minor ... [One line in a table headed *Common diatonic seventh chords in minor*:] __º7_____viiº7__" (*Tonal harmony*, Kostka, Stefan and Payne, Dorothy, McGraw-Hill, 3rd edition 1995, pp. 64–65).

[34] This is because the third of the triad does not belong to the natural minor scale or Aeolian mode of C minor (C, D, E♭, F, G, A♭, B♭). This highly restrictive interpretation is effectively equivalent to the idea that diatonic triads are those drawn from the notes of the major scale alone, as this source rather roughly puts it: "Diatonic chords are wholly contained within a major scale" (Harrison, Mark, *Contemporary Music Theory – Level Two*, 1999, p. 7).

[35] Often the content of "diatonic harmony" in this sense will include such harmonic resources as diminished sevenths on the leading note – possibly even in major keys – even if the text uses a classification for chords that should exclude those resources.

[36] Some of these are chords "borrowed" from a key other than the prevailing key of a piece; but some are not: they are derivable only by chromatic alteration.

[37] "*Diatonic harmonies* are those built on the seven degrees of whatever major or minor diatonic scale is being used. *Chromatic harmonies* are those built on, or using, the five non-diatonic degrees of the scale" *Music for Our Time*, Winter, Robert, Wadsworth, 1992, p. 35. (Strictly, there is an uncertainty to be noted here, involving harmonies that would be diatonic because they are built on unaltered degrees of a diatonic scale, but chromatic because they include a non-diatonic note: D–F♯–A in C major, for example. But the intention is clearly that such harmonies are chromatic.)

[38] Tischler, H. (1958). "Re: Chromatic Mediants: A Facet of Musical Romanticism". *Journal of Music Theory* **2** (1): 94–97. doi:10.2307/842933. JSTOR 842933.

[39] "... most chromatic harmony can be read as diatonic harmony with chromatic inflection", a view attributed to Simon Sechter in *New Grove*, "Analysis", §II: History 3.

[40] "A *chromatic progression* is one between harmonies having no diatonic relationship, harmonies which do not coexist in any single diatonic system of key and mode. For this purpose, the harmonic form of the minor scale is considered the tonal-harmonic basis of its diatonic system. A usual characteristic of the chromatic progression is *chromatic inflection* – the change of one or more notes from one form (sharp, natural, or flat) to another" Wallace Berry, *Form in Music* (Prentice-Hall, 1966), pp. 109–110, note 5.

[41] Wallace Berry, *Form in Music* (Prentice-Hall, 1966), pp. 109–110, note 5.

[42] "In [an example] the change from major to minor is supported by the chromatic progression ... in the bass" *Structural Functions of Harmony*, Schoenberg, Arnold, Faber & Faber, 1983, p. 54.

[43] See *New Grove Online*, "Musica Ficta", I, ii, cited earlier.

[44] See *Form in Music*, Berry, Wallace, Prentice-Hall, 1966, pp. 109–110, note 5. The author even includes movement between tonic and Neapolitan sixth harmonies (in both major and minor), because there exists some diatonic system in which both harmonies occur. With C major, for example, both occur in the subdominant minor, F minor.

[45] Berry, *Form in Music*, p. 125, note 2.

[46] *Twentieth-Century Harmony*, Persichetti, Vincent, Norton, 1961, pp. 50–51. Persichetti also makes an exceptional use of the term *diatonic scale* in this context: "Diatonic scales of five tones are harmonically limited ...".

[47] Zweifel, P. F. (1996). "Generalized Diatonic and Pentatonic Scales: A Group-Theoretic Approach". *Perspectives of New Music* **34** (1): 140–161. doi:10.2307/833490. JSTOR 833490.

[48] Rahn, J. (1996). "Turning the Analysis around: Africa-Derived Rhythms and Europe-Derived Music Theory". *Black Music Research Journal* **16** (1): 71–89. doi:10.2307/779378. JSTOR 779378.

27.12 Bibliography

27.12.1 Diatonic

Published sources for "diatonic", in Common Practice music.

- The sources cited below are sorted into three groups, depending on what they say about the term *diatonic*:
  - those that explicitly or implicitly exclude the harmonic and melodic minors, along with the consequences for intervals, etc.;
  - those that include the harmonic and melodic minors, with consequences; and
  - those that are ambiguous, inconsistent, or anomalous.
- In cited text below, relevant portions have been highlighted in **bold**, which has been added for emphasis.

Exclusive

Excluding harmonic and melodic minor scales:

- Scholes, Percy; Nagley, J. & Temperley N. (2002). "Scale". In Alison Latham. *The Oxford Companion to Music (subscription)*. Oxford University Press. Retrieved 2008-07-23. (Web)
  - Scholes, Percy; Nagley, J. & Temperley N. (2002). "Scale". In Alison Latham. *The Oxford Companion to Music*. London: Oxford University Press. p. 1106. ISBN 0-19-866212-2. OCLC 59376677. (Print)

> Scale ... 3. **Diatonic Scale**: ... The sixth and seventh degrees of the minor scale are unstable and result in two forms, **neither of them diatonic**: the **harmonic minor**, with the characteristic interval of an augmented 2nd; and the **melodic minor** ...

- **Grove Music Online** (see p. 295 in the print version)

> **Diatonic** (from Gk. dia tonos: 'proceeding by whole tones').
>
> Based on or derivable from an octave of seven notes in a particular configuration, as opposed to chromatic and other forms of scale. **A seven-note scale is said to be diatonic when its octave span is filled by five tones and two semitones**, with the semitones maximally separated, for example **the major scale (T–T–S–T–T–T–S)**. The **natural minor** scale and the **church modes** (see Mode) are also diatonic.
>
> [But see the same source, *Grove Music Online*, below also.]

- **The Harvard Dictionary of Music** 4th edition, p. 239

  > **Diatonic**: (1) A scale with seven pitches (heptatonic) that are adjacent to one another on the circle of fifths; thus, one in which each letter name represents only a single pitch and **which is made up of whole tones and semitones arranged in the pattern embodied in the white keys of the piano keyboard**; hence, **any major or *pure minor* scale and any church mode** as distinct from the chromatic scale.

- **Elements of Musical Composition**, Crotch, William, 1830 [reproduced 1991, Boethius Press, Aberystwyth, Wales], pp. 21–22

  > In modern music, the seventh note *Si* is often made one semitone higher, and then the scale of the minor key becomes chromatic. ... The sixth and seventh notes are both occasionally altered at the same time, and then also the scale is chromatic. ... This is the usual method of ascending the minor key, but in descending, the ancient diatonic scale is commonly used.
  >
  > [A rare instance of classifying the harmonic minor and the ascending melodic minor as *chromatic*.]

- **The Theory and Practice of Tone-Relations**, Goetschius, Percy, Schirmer, 1931 edition

  > [p. 4] **This diatonic scale comprises the tones of the *major mode***, so designated for reasons given later. Upon examination it is found that the contiguous intervals of the diatonic scale, unlike those of **the natural scale** [Goetschius's term for a series of pitches rising by fifths, starting from F and ending and B, with C identified as the "keynote"; see p. 3], are *not* uniform, but differ as follows:
  >
  > [A diagram is shown of a C major scale with slurs pointing out the semitones between scale steps 3 and 4, and 7 and 8.]
  >
  > [p. 33] The line of research and argument [above] proves that, of the two modes recognized and employed in modern music, that one known as major (because its prin. triads have a major third) is the *natural* one.
  >
  > The other, i.e., the *minor* mode, is consequently to be regarded as an unnatural or *artificial* mode, and is accounted for as an *arbitrary modification of the natural major mode*.
  >
  > ...
  >
  > The scale thus obtained is called the *harmonic* minor mode. It is the only theoretically accurate minor scale, [... .]
  >
  > [Goetschius's stance is unusual in not recognising any scale other than the major as diatonic; he does not mention the so-called "natural" minor scale as an entity in its own right, but considers the harmonic minor as the basic minor form, derived directly from the major by alteration of the third and sixth scale-steps. Later (pp. 104–106) he discusses the melodic minor scale, and the fact that the third scale-step is "the only distinctive tone between the major form and the various minor forms" (p. 105).]

- Clough, J. (1957). "The Leading Tone in Direct Chromaticism: From Renaissance to Baroque". *Journal of Music Theory* **1** (1): 2–21. JSTOR 843089.

  > Chromaticism being essentially the antonymn [*sic*] of the more restrictive term diatonicism, its precise definition rests on a series of definitions beginning with the concept diatonic system:
  >
  > - diatonic system
  >
  >   > a succession of whole steps and half steps, of indefinite compass, in which the half steps are separated alternately by two whole steps and three whole steps
  >
  > - **diatonic**
  >
  >   > **consisting entirely of tones from a single diatonic system**
  >
  > - diatonicism
  >
  >   > the use of diatonic collections of tones

- chromatic

  not consisting entirely of tones from a single diatonic system

- chromaticism

  the use of chromatic collections of tones

[... During] the past two hundred and fifty years, when extensive deviation from it and abandonment of it have become the norm of practice, the [diatonic] system has persisted as an important framework of tonal organization. Without doubt, this simple succession of whole and half steps is among the most deeply rooted facts of our musical culture.

In view of its historical pre-eminence alone, the system deserves to be represented in its pure form by such a basic theoretical concept as *diatonic*. **Modern abstractions such as the harmonic minor and so called "ascending melodic" minor scales, which are sometimes referred to as diatonic, cannot be reconciled with the above definitions without the term diatonic becoming an unwieldy and theoretically useless catch-all.** [Reference to footnote.]

> [Footnote:] 1. In this connection much confusion derives from the accepted meaning of the expression *chromatic scale*. (Clearly, the harmonic minor scale is not the chromatic scale; it is therefore diatonic, or so the reasoning goes.) If the presently accepted meaning of *chromatic scale* is to be retained, we must content ourselves with the paradox that the harmonic minor and "ascending-melodic" minor scales, while inherently chromatic, are not "chromatic scales".
>
> Here it might be stated also that, while I am entirely convinced of the soundness of the above definitions, the reader must realize that any doubts he may entertain regarding them can be in no way damaging to the principle to be derived by their use. So long as the concept of chromaticism, as defined above, is clearly understood, I have no essential objection to the reader's substituting his own term for it throughout the article. Universally accepted nomenclature is a desirable objective, but, unfortunately, it sometimes lags behind theoretical thought.

[A rare detailed articulation of the "exclusive" stance, exceptional for its mentioning and analysing the alternative "inclusive" stance.]

Inclusive

Including harmonic and melodic minor scales:

- Scholes, Percy (1955). "Diatonic and chromatic". *The Oxford Companion to Music* (9th ed.). London: Oxford University Press. p. 291.

  > **Diatonic and Chromatic**: ... The diatonic scales are the major and minor, made up of tones and semitones (**in the case of the harmonic minor scale, also an augmented second**), as distinct from the chromatic...

- **Oxford Concise Dictionary of Music** (Online ; current print edition is the same)

  > For the older European scales, used in the Church's plainsong and in folk song, see modes. Two of these ancient modes remained in use by composers, when the other 10 were almost abandoned, and **these are our major and minor scales – the latter, however, subject to some variations in its 6th and 7th notes**. Taking C as the keynote these scales (which have provided the chief material of music from about AD 1600 to 1900) run as follows: [than the first figure in the article, showing the major scale on C, then the harmonic minor on C, then the ascending and descending melodic on C; text continues immediately with:] **The major and minor scales are spoken of as DIATONIC SCALES, as distinct from a scale using nothing but semitones, which is the CHROMATIC SCALE,** ...

- **Music Notation and Terminology**, Gehrkens, Karl Wilson, Barnes, NY, 1914

  > [p. 79] There are three general classes of scales extant at the present time, viz.: (1) Diatonic; (2) Chromatic; (3) Whole-tone.
  >
  > [p. 80] The word diatonic means "through the tones" (i.e., through the tones of the key), and is applied to both major and minor scales of our modern

tonality system. **In general a diatonic scale may be defined as one which proceeds by half-steps and whole-steps. There is, however, one exception to this principle, viz., in the progression six to seven in the harmonic minor scale**, which is of course a step-and-a-half.

- **Tonal Harmony in Concept and Practice**, Forte, Allen, NY, Holt, Rinehart, and Winston, 3rd edition, 1979, p. 14

  The diatonic minor scale therefore has three forms: natural, melodic, and harmonic.

- **The New Penguin Dictionary of Music**, Jacobs, Arthur, Penguin, 4th edition (1977) reprinted with revisions (1986)

  [p. 108] *diatonic*, pertaining to a given major or minor key (opposite of CHROMATIC); so ***diatonic scale*, any one of the major or minor scales**; ...

  [pp. 246–247] *major, minor*, ... The *minor* scale is divided for theoretical purposes into three types, [followed by an equal treatment of natural, melodic, and harmonic minor scales, with figures showing each form]

- **Harmony: Its Theory and Practice**, Prout, Ebenezer, Augener, 16th edition 1901, Chapter I, p. 3

  8. A SCALE is a succession of notes arranged according to some regular plan. Many different kinds of scales have been used at various times and in various parts of the world; **in modern European music only two are employed, which are called the *diatonic* and the *chromatic* scale**.

  9. The word "diatonic" has already been explained in §6 as meaning "through the degrees". A diatonic scale is a succession of notes in which there is one note, neither more nor less, on each degree of the staff – that is to say, on each line and space. [Reference to Chapter II, p. 17, where the sources of the modern scales in the old system of modes are explained.] **There are two varieties of the diatonic scale, known as the *major* (or greater) and *minor* (or less) scale** from the nature of the interval between the first and third notes of the scale. [Two figures, showing an ascending octave of the C major scale (Ex. 4) and of the C harmonic minor scale (Ex. 5).] Other forms of the minor scale frequently to be met with will be explained later. [The melodic is introduced and explained in Chapter VII, pp. 80–83, §§ 206–210.]

- **Music History and Theory**, Clendinnen, William, Doubleday, 1965, p. 23

  Western music made from about 1680–1880 made use of a system of *diatonic scales*, comprising certain arrangements of whole tones (T) and semitones (S) such as the *major* ... the *melodic minor* ... and the *harmonic minor* (T-S-T-T-S-T½-S).

- **Harmony**, Piston, Walter, DeVoto, Mark, Norton, 5th edition, 1987, pp. 4–5

  The tones that form the interval are drawn from *scales*. The most familiar of these are **the two *diatonic* scales of seven notes each, called the *major scale* and the *minor scale*. Tonal music, which includes most music written between 1700 and 1900, is based on diatonic scales.**

  The difference between the major and minor scales is found in the distribution of whole steps and half steps above a given starting point. [... C major scale as one case; Example 1–2, showing the scale and its steps and half steps.]

  There are three different forms of the minor scale. The *natural minor scale* has three tones that are different from corresponding tones in the major scale. Some of these same tones are also found in the other forms, as shown here. [Example 1–3, showing five forms of scales on C: major, natural minor, harmonic minor, melodic minor ascending (all shown ascending); and melodic minor descending.]

  All of the possible pitches in common use, considered together, constitute the *chromatic scale*. [Example 1–4, showing an ascending and descending chromatic scale; explanation of the chromatic scale. ...]

  Any particular diatonic scale is a seven-note subset of the twelve-note chromatic scale.

Other

Vague, inconsistent, or anomalous use:

- **Grove Music Online**

  Diatonic (same article as cited above) ... An **interval** is said to be **diatonic** if it is **available within a diatonic scale**. The following intervals and their compounds are all diatonic: minor 2nd (S), major 2nd (T), minor 3rd (TS), major 3rd (TT), perfect 4th (TTS), perfect 5th (TTST), minor 6th (STTTS), major 6th (TTSTT), minor 7th (TSTTTS), major 7th (TTSTTT) and the octave itself. **The tritone, in theory diatonic according to this definition, has traditionally been regarded as the alteration of a perfect interval, and hence chromatic**; it may be either a semitone more than a perfect 4th (augmented 4th: TTT) or a semitone less than a perfect 5th (diminished 5th: STTS).

- **Grove Music Online**

  Minor (i). (1) The name given to **a diatonic scale whose octave, in its natural form**, is built of the following ascending sequence, in which T stands for a tone and S for a semitone: T–S–T–T–S–T–T). The note chosen to begin the sequence, called the key note, also becomes part of the name of the scale; a D minor scale, for instance, consists of the notes D–E–F–G–A–B♭–C–D. In practice, however, some notes of the scale are **altered chromatically** to help impart a sense of direction to the melody. The **harmonic minor** scale has a raised seventh, in accordance with the need for a major triad on the fifth step (the Dominant chord). The melodic minor scale has a raised sixth and a raised seventh when it is ascending, borrowing the leading-note function of the seventh step from the major scale; in descending, though, it is the same as the natural minor scale.

- **The Cambridge History of Western Music Theory**, ed. Thomas Christensen, 2004

  [Records different usages by different major theorists.]

- **Encyclopaedia Britannica** (Online: consulted in April 2007; 2005 CD-ROM version is the same.)

  Diatonic. ... The "harmonic" minor that results is, strictly speaking, **no longer a diatonic scale, unlike "melodic" minor**, which simply borrows its upper tetrachord from the parallel major, i.e., the major scale beginning and ending on the same pitch.

  [This accepts the ascending melodic as diatonic.]

- **Encyclopaedia Britannica** (Online: consulted in December 2007.)

  Diatonic. [I]n music, **any stepwise arrangement of the seven "natural" pitches (scale degrees) forming an octave without altering the established pattern of a key or mode – in particular, the major and natural minor scales.** Some scales, including pentatonic and whole-tone scales, are not diatonic because they do not include the seven degrees. ... In the natural minor scale, the half steps occur at II-III and V-VI. Given the crucial importance of the so-called leading tone (the seventh degree of the major scale) in diatonic harmony, however, **the natural minor scale regularly becomes subject to chromatic alteration** (in this case, the raising by a half step) of its seventh degree (the harmonic minor form) and often the sixth degree as well (the melodic minor form of the scale, used in an ascending melody). **The harmonic minor is, strictly speaking, not really a scale**; it is used normally not melodically but as a source set for constructing harmony. The upper tetrachord of the ascending melodic minor scale is identical with that of the major scale. ... **The diatonic scale, as a model, is contrasted with the chromatic scale of 12 pitches**, corresponding to the white and black notes of the piano keyboard considered together. ... An accidental sign in front of a note normally signifies **either that the tone is notated as the sixth or seventh degree of the minor scale, or that the tone is a chromatic tone (it does not belong to the particular diatonic scale being used in the harmony of the moment)**.

  [The status of the harmonic and melodic minor as *diatonic* is left uncertain. Treatment of the alteration of the sixth and seventh degrees in minor is self-contradictory: at first those degrees are "subject to chromatic alteration"; but later such alterations are mentioned separately from and *distinguished* from "chromatic tones".]

- **Elementary Training for Musicians** Hindemith,

Paul, 2nd edition, 1949, p. 58

> ... (diatonic = consisting of whole- and half-tone steps)...
>
> [This definition fails to *exclude* the ascending melodic as diatonic, and fails to *include* the harmonic minor.]

- Dunsby, Jonathan (2002). "Diatonic". In Alison Latham. *The Oxford Companion to Music (subscription)*. London: Oxford University Press. Retrieved 2008-07-23.

> **diatonic** (from Gk. dia tonikos, 'at intervals of a tone). In the major–minor tonal system, **a diatonic feature** – which may be a single note, an interval, a chord, or an extended passage of music – is **one that uses exclusively notes belonging to one key**. In practice, **it can be said to use a particular scale, but only with the proviso that the alternative submediants and leading notes of harmonic and melodic minor allow up to nine diatonic notes**
>
> Compared with the seven available in a major scale. The exact intention with regard to classification of the harmonic and melodic minor scales is unclear, and likely to be inconsistent.

- **Collins Pocket Dictionary of Music**, Collins, 1982 [abridged from *Collins Encyclopedia of Music*, eds. Westrup, J, and Harrison, F, revised edition 1976]

> **Diatonic** ... In minor keys [the] sharpened sixth and seventh are in such common use, though not strictly proper to [the] key, that they are also regarded as diatonic ...
>
> **Scale** ... Modern *diatonic* scale as 2 modes: major ... and minor (TSTTSTT). Latter only has theoretical existence; in practice has 2 forms, both of which involve element of chromaticism in treatment of leading note: [forms of harmonic and ascending and descending melodic are given].
>
> [See note for the entry immediately above.]

- **Theory of Harmony** Schoenberg, Arnold, (translation of 3rd edition, 1922), 1983, p. 32

> In the seven chords that we build on the seven tones of the major scale we use no tones other than these same seven – *the tones of the scale*, the *diatonic tones*.
>
> [Harmonic and melodic minor scales aren't necessarily excluded. The intention is unclear.]

- **A Dictionary of Musical Terms** Baker, Theodore, 1923 edition

> **Diatonic**: (In modern usage) By, through, with, within, or embracing the tones of the standard major or minor scale.
>
> [The phrase "standard major or minor scale" is ambiguous, and could include all forms of the minor.]

- **Music for Our Time**, Winter, Robert, Wadsworth, 1992, pp. 28–29

> ... Western music settled on **two diatonic patterns**, known today as the *major* scale and the *minor* scale. ... The minor scale results from flatting (lowering by half a step) the third and sixth degrees of the major scale. ... it is frequently smoothed out by [alterations to the sixth and seventh degree. ...] this form of the minor scale is called the *melodic minor scale*.
>
> [The precise interpretation of *patterns* in *two diatonic patterns* is open to dispute. On one reading, these patterns are more general and flexible, and the *minor* pattern remains diatonic when it is varied as the author describes. By that reading, the definition of *diatonic scale* is not anomalous, but includes all standard forms of the minor scale. On another reading, *pattern* is taken to mean "exact configuration of tones and semitones"; by that reading, the definition is barely coherent (since a scale constrained to conform to such a strict configuration cannot be "smoothed out" by the alterations mentioned and yet retain the pattern that the author identifies as "the minor scale"). This second reading entails that among the minors only the harmonic form is "diatonic".]

Chapter 28

Diatonic scale

Diatonic scale on C, equal tempered Play and just Play .

Pythagorean diatonic scale on C Play . A plus sign (+) indicates the syntonic comma.

In music theory, a **diatonic scale** (or **heptatonia prima**) is a scale composed of seven distinct pitch classes. The diatonic scale includes five whole steps and two half steps for each octave, in which the two half steps are separated from each other by either two or three whole steps, depending on their position in the scale. This pattern ensures that, in a diatonic scale spanning more than one octave, all the half steps are maximally separated from each other (i.e. separated by at least two whole steps). The word "diatonic" comes from the Greek διατονικός, meaning progressing through tones.[1]

The seven pitches of any diatonic scale can be obtained using a chain of six perfect fifths. For instance, the seven natural pitches which form the C-major scale can be obtained from a stack of perfect fifths starting from F:

F—C—G—D—A—E—B

This property of the diatonic scales was historically relevant and possibly contributed to their worldwide diffusion because for centuries it allowed musicians to tune musical instruments easily by ear (see Pythagorean tuning).

Any sequence of seven successive natural notes, such as C-D-E-F-G-A-B, and any transposition thereof, is a diatonic scale. Piano keyboards are designed to play natural notes, and hence diatonic scales, with their white keys. A diatonic scale can be also described as two tetrachords separated by a whole tone.

The term *diatonic* originally referred to the diatonic genus, one of the three genera of the ancient Greeks. In musical set theory, Allen Forte classifies diatonic scales as set form 7–35.

This article does not include alternative seven-note diatonic scales such as the harmonic minor or the melodic minor.

28.1 History

Diatonic scales are the foundation of the European musical tradition. Western harmony from the Renaissance until the late 19th century is based on the diatonic scale and the unique hierarchical relationships, or diatonic functionality, created by this system of organizing seven notes.

The modern major and minor scales are diatonic, as were all of the 'church modes'. What are now called major and minor were in reality – during the medieval and Renaissance periods – only two of eight modes ('church modes') based on the same diatonic notes (but forming different scales when the starting note was changed). Depending on which of the seven notes is used as the beginning, the positions of the intervals, the half-steps, end at different distances from the starting tone, hence obtaining seven different scales or modes that are, as already mentioned, deduced from the diatonic scale. By the end of the Baroque period, the notion of musical key was established—based on a central triad rather than a central tone. Major and minor scales came to dominate until at least the start of the 20th century, partly because their intervallic patterns are suited to the reinforcement of a central triad. Some church modes survived into the early 18th century, as well as appearing occasionally in classical and 20th-century music, and later in modal jazz.

28.1.1 Prehistory

There is one claim that the 45,000 year-old Divje Babe Flute uses a diatonic scale, but there is no proof or consensus it is even a musical instrument.[2]

There is evidence that the Sumerians and Babylonians

used some version of the diatonic scale.[3] This derives from surviving inscriptions that contain a tuning system and musical composition. Despite the conjectural nature of reconstructions of the piece known as the Hurrian songs from the surviving score, the evidence that it used the diatonic scale is much more soundly based. This is because instructions for tuning the scale involve tuning a chain of six fifths, so that the corresponding circle of seven major and minor thirds are all consonant-sounding, and this is a recipe for tuning a diatonic scale. See Music of Mesopotamia.

9,000-year-old flutes found in Jiahu, China indicate the evolution, over a period of 1,200 years, of flutes having 4, 5 and 6 holes to having 7 and 8 holes, the latter exhibiting striking similarity to diatonic hole spacings and sounds.[4]

28.2 Theory

Using the twelve notes of the chromatic scale, twelve of each of the three major scales (those with a major third/triad: Ionian, Lydian, and Mixolydian), twelve of each of the three minor scales (those with a minor third/triad: Dorian, Phrygian, and Aeolian), and twelve Locrian scales can be played, totaling eighty-four diatonic scales. The modern musical keyboard, with its black keys grouped in twos and threes, is essentially diatonic; this arrangement not only helps musicians to find their bearings on the keyboard, but simplifies the system of key signatures compared with what would be necessary for a continuous alternation of black and white keys. The black (or "short") keys were an innovation that allows the adjacent positioning of most of the diatonic whole-steps (all in the case of C major), with significant physical and conceptual advantages.

28.3 Analysis

The modern piano keyboard is based on the interval patterns of the diatonic scale. Any sequence of seven successive white keys plays a diatonic scale.

In music of the broadly western classical tradition the pattern of seven intervals separating the eight notes of an octave (see heptatonic scale) can be represented in three ways, which are equivalent to each other. For instance, for a major scale these intervals are:

- *T-T-S-T-T-T-S*: where *S* means semitone; *T* means tone
- *2–2–1–2–2–2–1*: where *1* means semitone; *2* means tone (2 semitones)
- *whole-whole-half-whole-whole-whole-half*: where *half* means semitone (half a tone); *whole* means tone.

28.3.1 Major scale

Main article: Major scale

The major scale or Ionian scale is one of the diatonic scales. It is made up of seven distinct notes, plus an eighth which duplicates the first an octave higher. The pattern of seven intervals separating the eight notes is T-T-S-T-T-T-S. In solfege, the syllables used to name each degree of the scale are "Do–Re–Mi–Fa–Sol–La–Ti–Do". A sequence of successive natural notes starting from C is an example of major scale, called C-major scale.

The eight degrees of the scale are also known by traditional names:

- 1st – Tonic (key note)
- 2nd – Supertonic
- 3rd – Mediant
- 4th – Subdominant
- 5th – Dominant
- 6th – Submediant
- 7th – Leading tone
- 8th – Tonic (Octave)

28.3.2 Natural minor scale

Main article: Minor scale

For each major scale, there is a corresponding natural minor scale, sometimes called its relative minor. It uses the same sequence of notes as the corresponding major scale, but starts from a different note. Namely, it begins on the sixth degree of the major scale and proceeds step by step to the first octave of the sixth degree. A sequence of successive natural notes starting from A is an example of natural minor scale, called A-minor scale.

The degrees of the natural minor scale have the same names as those of the major scale, except the seventh degree, which is known as the subtonic because it is a whole step below the tonic. The term leading tone is generally reserved for seventh degrees that are a half step (semitone) away from the tonic, as is the case in the major scale or the harmonic minor scale (and the melodic minor, ascending). In solfege the scale degrees are named in two different ways: either "La–Ti–Do–Re–Mi–Fa–Sol–La" or "Do–Re–Me–Fa–Sol–Le–Te–Do."

Besides the natural minor scale, five other kinds or modes of scales can be obtained from the notes of a major scale, by simply choosing a different note as the starting note or tonic. All these scales meet the definition of diatonic scale.

28.3.3 Modes

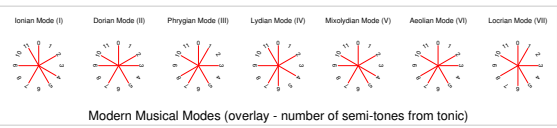
Main article: Mode (music)

The whole collection of diatonic scales as defined above can be divided into seven different modes.

As explained above, all major scales use the same interval sequence T-T-s-T-T-T-s. From the modal point of view, this interval sequence is called the *Ionian mode*. It is one of the seven modern modes. Taking any major scale, a new scale is obtained by taking a different degree of the major scale as the tonic. With this method, from each major scale it is possible to generate six other scales or modes, each characterized by a different interval sequence:

For the sake of simplicity, the examples shown above are formed by natural notes (also called "white-notes", as they can be played using the white keys of a piano keyboard). However, any transposition of each of these scales is a valid example of the corresponding mode. In other words, transposition preserves mode.

The whole set of diatonic scales is commonly defined as the set composed of these seven natural-note scales, together with all of their possible transpositions. As discussed elsewhere, different definitions of this set are sometimes adopted in the literature.



Pitch constellations of the modern musical modes

28.3.4 Diatonic scales and tetrachords

A diatonic scale can be also described as two tetrachords separated by a whole tone. For example, under this view the two tetrachord structures of C major would be:

[C-D-E-F]-[G-A-B-C]

and the natural minor of A would be:

[A-B-C-D]-[E-F-G-A].

The set of intervals within each tetrachord comprises two tones and a semitone.

28.4 Properties

The diatonic scale as defined above has specific properties that make it unique among seven-note scales. In other words, no other kind of scale has the same properties:

- It is obtained from a chain of six successive perfect fifths. For instance, the seven natural pitches which form the C-major scale can be obtained from a chain of perfect fifths starting from F (F—C—G—D—A—E—B)
- It is either a sequence of successive natural notes (such as the C-major scale, C-D-E-F-G-A-B, or the A-minor scale, A-B-C-D-E-F-G) or a transposition thereof.
- It can be written using seven consecutive notes without accidentals on a staff with a conventional key signature, or with no signature. This is because the staff is purposely designed to represent diatonic scales.

David Rothenberg conceived of a property of scales he called *propriety*, and around the same time Gerald Balzano independently came up with the same definition in the more limited context of equal temperaments, calling it *coherence*. Rothenberg distinguished *proper* from a slightly stronger characteristic he called *strictly proper*. In this vocabulary, there are five proper seven-note scales in 12 equal temperament. None of these is strictly proper, i.e., coherent in the sense of Balzano; but in any system of meantone tuning with the fifth flatter than 700 cents, they are strictly proper. The scales are the diatonic, ascending minor, harmonic minor, harmonic major, and locrian major scales; of these, all but the last are well-known and constitute the backbone of diatonic practice when taken together.

Among these four well-known variants of the diatonic scale, the diatonic scale itself has additional properties of what has been called *simplicity*, because it is produced by iterations of a single generator, the meantone fifth. The scale, in the vocabulary of Erv Wilson, who may have been the first to consider the notion, is sometimes called a MOS scale.

The diatonic collection contains each interval class a unique number of times.[5] Diatonic set theory describes the following properties, aside from propriety: maximal

evenness, Myhill's property, well formedness, the deep scale property, cardinality equals variety, and structure implies multiplicity.

28.5 Tuning

In just intonation the diatonic scale is tuned (see Ptolemy's intense diatonic scale):

In Pythagorean tuning the diatonic scale is:

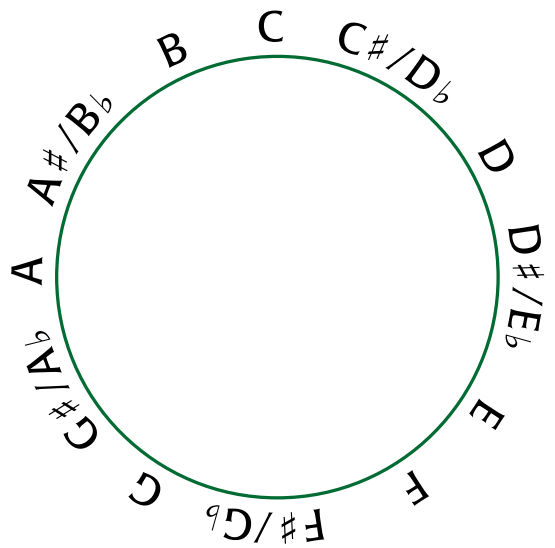
Chapter 29

Chromatic scale



Chromatic scale drawn as a circle: each note is equidistant from its neighbors, separated by a semitone of the same size.

The **chromatic scale** is a musical scale with twelve pitches, each a semitone above or below another. On a modern piano or other equal-tempered instrument, all the semitones are the same size (100 cents). In other words, the notes of an equal-tempered chromatic scale are equally spaced. An equal-tempered chromatic scale is a nondiatonic scale having no tonic because of the symmetry of its equally spaced notes.[1]

Chromatic scale on C: full octave ascending and descending Play in equal temperament or Play in Pythagorean tuning .

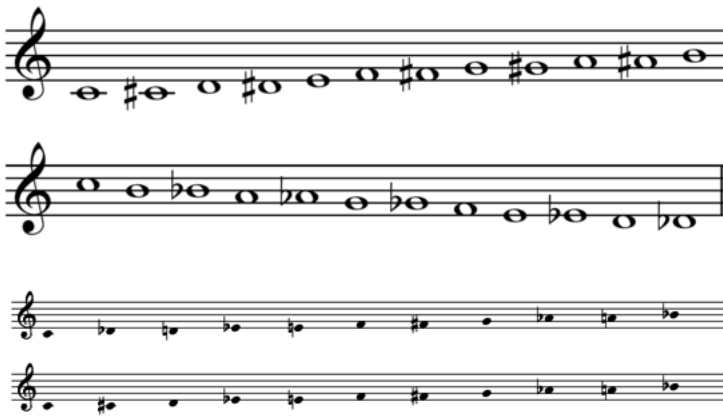
The most common conception of the chromatic scale before the 13th century was the Pythagorean chromatic scale. Due to a different tuning technique, the twelve semitones in this scale have two slightly different sizes. Thus, the scale is not perfectly symmetric. Many other tuning systems, developed in the ensuing centuries, share a similar asymmetry. Equally spaced pitches are provided only by equal temperament tuning systems, which are widely used in contemporary music.

The term *chromatic* derives from the Greek word *chroma*, meaning *color*. Chromatic notes are traditionally understood as harmonically inessential embellishments, shadings, or inflections of *diatonic* notes.

29.1 Notation

The chromatic scale may be notated in a variety of ways.

Ascending and descending:[1]



The chromatic scale has no set spelling agreed upon by all. Its spelling is, however, often dependent upon major or minor key signatures and whether the scale is ascending or descending. The images above, therefore, are only examples of chromatic scale notations. As an abstract theoretical entity (that is, outside a particular musical context), the chromatic scale is usually notated such that no scale degree is used more than twice in succession (for instance G flat - G natural - G sharp).

29.2 Non-Western cultures

- The ancient Chinese chromatic scale is called *Shí-èr-lǜ*. However, "it should not be imagined that this gamut ever functioned as a scale, and it is erroneous to refer to the 'Chinese chromatic scale', as some Western writers have done. The series of twelve

notes known as the twelve *lü* were simply a series of fundamental notes from which scales could be constructed."[2]

- The Indian solfège, i.e. sargam, makes up the twelve notes of the chromatic scale with respective sharps and flats.

29.3 Total chromatic

The *total chromatic* (or *aggregate*[3]) is the set of all twelve pitch classes. An *array* is a succession of aggregates.[3] See also: Tone row.

F♯		5		6		7	1		2		3	4

Major scales

The **major scale** or **Ionian scale** is one of the most commonly used musical scales, especially in Western music. It is one of the diatonic scales. Like many musical scales it is made up of seven notes: the eighth duplicates the first at double its frequency so that it is called a higher octave of the same note (from Latin "octavus", the eighth).

The simplest major scale to write is C major, the only major scale not to require sharps or flats:

C-D-E-F-G-A-B-C (🔊 C major scale)

The major scale had a central importance in European music, particularly in the common practice period and in popular music, owing to the large number of chords that can be formed from it. In Hindustani classical music it is known as *Bilaval*.

30.1 Structure

A major scale is a diatonic scale. The sequence of intervals between the notes of a major scale is:

- whole, whole, half, whole, whole, whole, half

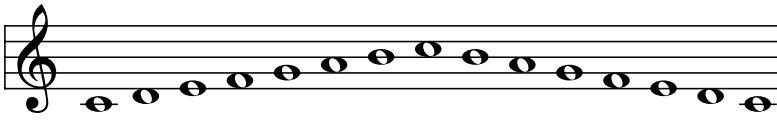
The pattern of whole and half steps characteristic of a major scale

where "whole" stands for a whole tone (a red u-shaped curve in the figure), and "half" stands for a semitone (a red broken line in the figure).

A major scale may be seen as two identical tetrachords separated by a whole tone. Each tetrachord consists of two whole tones followed by a semitone:

- whole, whole, half.

30.1.1 Scale degrees



Main article: Degree (music)

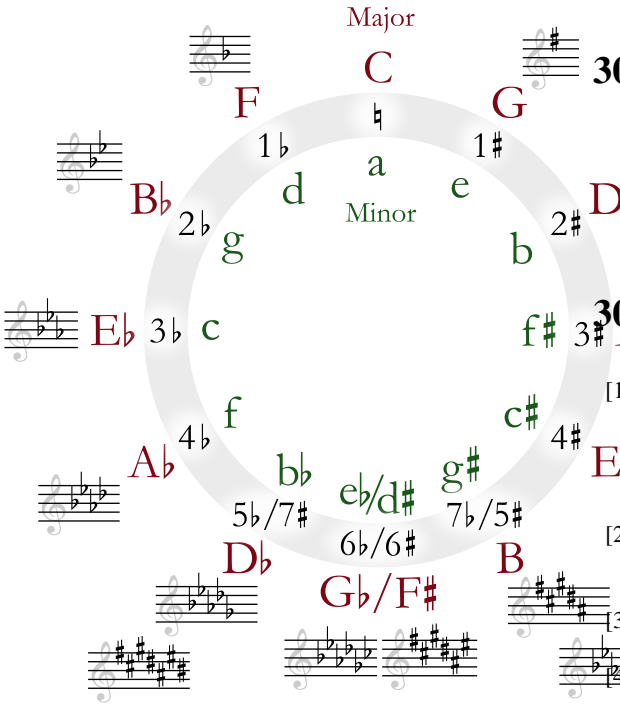
- 1st – Tonic- key note
- 2nd – Supertonic
- 3rd – Mediant
- 4th – Subdominant
- 5th – Dominant
- 6th – Submediant
- 7th – Leading tone
- 8th – Tonic (or Octave)

30.1.2 The circle of fifths

Main article: Circle of fifths

The circle of fifths, first described in 1728 by Johann David Heinichen in his book *Der General-bass*, has been

used ever since as a means of illustrating the relative harmonic distance between musical keys.[1]



The numbers inside the circle show the number of sharps or flats in the key signature, with the sharp keys going clockwise, and the flat keys counterclockwise from C major (which has no sharps or flats.) The circular arrangement depends on enharmonic relationships in the circle, usually reckoned at six sharps or flats for the major keys of F♯ = G♭ and D♯ = E♭ for minor keys.[1] Seven sharps or flats make major keys (C♯ major or C♭ major) that may be more conveniently spelled with five flats or sharps (as D♭ major or B major).

30.2 Broader sense

The term "major scale" is also used in the names of some other scales whose first, third, and fifth degrees form a major triad.

The harmonic major scale[2][3][4] has the sixth degree lowered. Example: C-D-E-F-G-A♭-B-C. It differs from the harmonic minor scale only by the third degree.

The **melodic major** scale[5] is the fifth mode of the jazz minor scale. Example: C-D-E-F-G-A♭-B♭-C. It differs from the Ionian scale by lowering the sixth and the seventh degrees and from the natural minor scale by raising the third degree. The combined scale that goes as Ionian ascending and as melodic major descending is also called melodic major: C-D-E-F-G-A-B-C-B♭-A♭-G-F-E-D-C (differs from melodic minor only by raising the third degree).[6]

The double harmonic major scale[7][8] has the second and the sixth degrees lowered. Example: C-D♭-E-F-G-A♭-B-C. It is the fifth mode of the Hungarian minor scale.

Chapter 31

Minor scale

For the simulated nuclear detonation, see Minor Scale.

In music theory, **minor scale** may refer to:

	C	C# Db	D	D# Eb	E	F	F# Gb	G	G# Ab	A	A# Bb	B
Bbm	2	3		4		5	6		7		1	
Fm	5	6		7		1		2	3		4	
Cm	1		2	3		4		5	6		7	
Gm	4		5	6		7		1		2	3	
Dm	7		1		2	3		4		5	6	
Am	3		4		5	6		7		1		2
Em	6		7		1		2	3		4		5
Bm		2	3		4		5	6		7		1
F#m		5	6		7		1		2	3		4
C#m		1		2	3		4		5	6		7
G#m		4		5	6		7		1		2	3
D#m		7		1		2	3		4		5	6

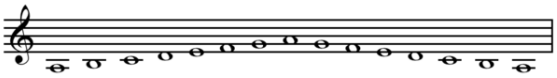
Natural minor scales

- a heptatonic scale whose first, third, and fifth scale degrees form a minor triad, that is, a 7-note scale in which the third note is a minor third (three semitones) above the first, and the fifth note is a perfect fifth (seven semitones) above the first. This includes the *natural minor*, *harmonic minor*, and *melodic minor* scales. A minor scale differs from a major scale in that the third degree in a major scale is a major third (four semitones) above the first degree. In other words, the third degree in a major scale is one semitone higher than in a minor scale.

- the **natural minor** scale, also known as Aeolian scale, taken by itself. When a major scale and a natural minor scale have the same key signature, they are relative keys. A natural minor scale has the same notes as its relative major scale, but is built starting from the sixth note of the relative major scale.

- the functional fusion of *natural minor*, *harmonic minor*, and *melodic minor* scales, as is used in Western classical music (*see* major and minor). A harmonic minor scale differs from a natural minor scale in that the seventh note is raised one semitone. Melodic minor scales raise both the sixth and seventh notes one semitone when ascending, but when descending, the sixth and seventh notes are flattened, producing the natural minor scale.

31.1 Natural minor scale



The A natural minor scale. Play

This pattern of whole and half steps characterizes the natural minor scales.

The natural minor scale follows the sequence of steps:

- whole, half, whole, whole, half, whole, whole

In semitones, this is

- two, one, two, two, one, two, two (2 1 2 2 1 2 2) (or T S T T S T T)

If the white keys on the piano are played beginning on the sixth step of the C-major scale, which is A, to the A an octave above, then a natural minor scale is produced. In this case the minor scale is called A-minor, and this minor scale has no accidentals (sharps or flats). A-minor is called the relative minor of C. Every major key has a relative minor, which starts on the sixth scale degree or step.

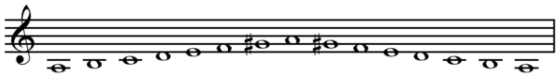
The natural minor scale can also be represented by the notation:

- 1 2 ♭3 4 5 ♭6 ♭7 8

Each degree of the scale, starting with the tonic (the first, lowest note of the scale), is represented by a number. Their difference from the major scale is shown. Thus a number without a sharp or flat represents a major (or perfect) interval. A number with a flat represents a minor interval, and a number with a sharp (though there are none in this example) represents an augmented interval. In this example, the numbers mean: 1=unison, 2=major second, ♭3=minor third, 4=perfect fourth, 5=perfect fifth, ♭6=minor sixth, ♭7=minor seventh, 8=octave. So, the natural minor scale consists of: 1, the tonic, followed by 2, a note a major second above the tonic, ♭3, a note a minor third above the tonic, and so forth, up to 8, a note an octave above the tonic.

In rock and popular music examples of songs in Minor Keys include The Moody Blues' "Nights in White Satin", Blondie's "Call Me", and Spinal Tap's "Lick My Love Pump".[1]

31.2 Harmonic minor scale



The A harmonic minor scale. Its seventh note is raised by a semitone. Play

The notes of the **harmonic minor** scale are the same as the natural minor except that the seventh degree is raised by one semitone, making an augmented second between the sixth and seventh degrees. The seventh degree, in a similar way to major scales, becomes a leading tone to the tonic because it is now only a semitone lower than the tonic, in contrast to the seventh degree in natural minor scales, which are a whole tone lower than the tonic (subtonic). A harmonic minor scale follows the sequence of steps:

- whole, half, whole, whole, half, whole-and-a-half, half

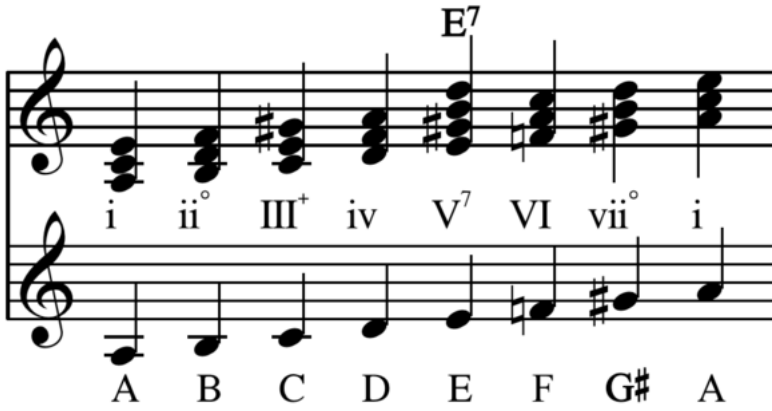
In semitones, this is

- two, one, two, two, one, three, one (2 1 2 2 1 3 1)

This can also be notated as:

- 1 2 ♭3 4 5 ♭6 7 8.

The scale is so named because it is a common foundation for harmonies (chords) used in a minor key. For example, in the key of A-minor, the V chord (the triad built on the note E) is normally a minor triad, which includes the seventh degree of the A-minor scale: G♮, as opposed to the raised seventh G♯ which would make a major triad in Harmonic Minor.



Play

Chords on degrees other than V may also include the raised seventh degree in minor keys, such as the diminished triad on VII itself (vii°); and also the augmented triad on III (iii+), which is not found in any "natural" harmony (that is, harmony based on notes of the major scale only, or the natural minor scale only). This augmented fifth chord (♯5 chord) played a part in the development of modern chromaticism.

The inversions of an augmented triad introduce no intervals (allowing for enharmonic equivalents) that are absent from its root position. The first inversion is enharmonically equivalent to a new augmented triad in root position. For example, the triad E♭–G–B in first inversion is G–B–E♭, enharmonically equivalent to the augmented triad G–B–D♯. The same is true for the second inversion. One chord, with various spellings, may therefore have various harmonic functions in various keys, which introduces ambiguous tonality and opens the door to chromatic possibilities exploited by J. S. Bach, for example, and of course by many later composers. A similar analysis applies to the diminished seventh chord, founded on the diminished triad on VII in minor keys and ambiguous for the same reasons as the augmented triad.

While it evolved primarily as a basis for chords, the harmonic minor with its augmented second is sometimes used melodically. Instances can be found in Mozart, and notably in Schubert (for example, in movement 1 of String Quartet 14, "Death and the Maiden"). In this role it is used descending far more commonly than ascending.

The harmonic minor is also occasionally referred to as the **Mohammedan scale**[2] as its upper tetrachord corresponds to the Hijaz jins, commonly found in Middle Eastern music. The harmonic minor scale as a whole is called *Nahawand-Hijaz*[3] in Arabic nomenclature, and as *Bûselik Hicaz*[4] in Turkish nomenclature. And as an Indian raga it is called *Kirwani*.

The Hungarian minor scale is similar to the harmonic minor scale but with a raised fourth degree. This scale is sometimes also referred to as "Gypsy Run", or alterna-

tively “Egyptian Minor Scale”, as mentioned by jazz legend Miles Davis who describes it in his autobiography as “something that I'd learned at Juilliard”.[5]

In popular music, examples of songs in harmonic minor include "Easy Please Me" by Katy B, which is a pop song, in rare instances, written in pure harmonic minor.

31.3 Melodic minor scale

The A melodic minor scale. When ascending, the sixth and seventh notes are both raised above the corresponding notes of the natural minor scale. The descending melodic minor scale is the same as the descending natural minor scale. Play

The distinctive sound of the harmonic minor scale is the interval between the (minor) sixth and (major) seventh degrees of the scale (in the case of A-minor, F and G♯), which is an augmented second. While some composers, notably Mozart, have used this interval to advantage in melodic composition, other composers, having felt it to be an awkward leap, particularly in vocal music, considered a whole step between these two scale degrees more conducive to smooth melody writing, so either the sixth scale degree was raised or the seventh flattened, in both cases by a semitone. Traditionally, music theorists have called these two options the **ascending melodic minor scale** (also known as **heptatonia seconda** and jazz minor scale) and **descending melodic minor scale** respectively. Note that the ascending melodic minor scale is the 5th mode of the Lydian Dominant or acoustic scale. The ascending melodic minor scale can be notated as

- 1 2 ♭3 4 5 6 7 8

While the descending is:

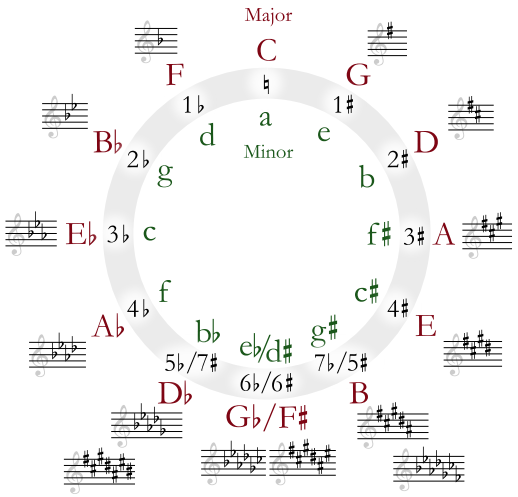
- 1 2 ♭3 4 5 ♭6 ♭7 8

In its upper tetrachord, the ascending melodic minor scale is identical to its major scale. The descending melodic minor scale is identical to the natural minor scale.

Composers have not been consistent in using these in ascending and descending melodies. Just as often, composers choose one form or the other based on whether one of the two notes is part of the most recent chord (the *prevailing harmony*). Particularly, to use the triad of the relative major—which is very common—since this is based on the third degree of the minor scale, the raised seventh degree would cause an augmented triad. Composers thus frequently require the lowered seventh degree found in the natural minor. In jazz, the descending aeolian is usually disregarded altogether.

Examples of the use of melodic minor in rock and popular music include Elton John's "Sorry Seems To Be The Hardest Word", which makes, “a nod to the common practice...by the use of F♯ [the leading-tone in G minor] as the penultimate note of the final cadence.”[6]

31.4 Finding key signatures



Circle of fifths showing major and minor keys and their signatures

Major and minor keys that share the same signature are *relative* to each other; so C-major is the relative major of A-minor, and C-minor is the relative minor of E♭-major. The relative major is a minor third above the tonic of the minor. For example, since the key signature of G-major has one sharp (see major scales for how to find this), its relative minor, E minor, also has one sharp in its key signature.

Music may be written in an enharmonic scale (e.g. C♯ minor, which only has four sharps in its key signature, compared to the theoretical eight flats required for D♭ minor). The following are enharmonic equivalents:

Double sharps/double flats can be written as accidentals, but not as part of a key signature. For example:

D♭ minor key signature: E♭ + A♭ + D♭ + G♭ + C♭ + F♭ + **B𝄫** (the B is now double flatted and therefore, notated **after** the single accidentals, which obviously do not include the B♭)

D♭ natural minor = D♭ E♭ F♭ G♭ A♭ **B𝄫** C♭ D♭

D♭ melodic minor (ascending and descending) = D♭ E♭ F♭ G♭ A♭ B♭ C D♭ C♭ **B𝄫** A♭ G♭ F♭ E♭ D♭

D♭ harmonic minor = D♭ E♭ F♭ G♭ A♭ **B𝄫** C D♭

31.5 Related modes

In the Western system, derived from the Greek system of modes, the principal scale that includes the minor third is the Aeolian mode, with the minor third also occurring in the Dorian mode and the Phrygian mode. Dorian is the same as minor mode except with a major sixth, and Phrygian mode is the same as minor mode except with a minor second. The Locrian mode contains the minor third but not the perfect fifth, so its root chord is diminished.

Chapter 32

Pentatonic scale

For the record label, see Pentatone (record label).

A **pentatonic scale** is a musical scale or mode with five notes per octave in contrast to a heptatonic (seven note) scale such as the major scale and minor scale. Pentatonic scales are very common and are found all over the world. They are divided into those with semitones (hemitonic) and those without (anhemitonic).

The first two phrases of the melody from Stephen Foster's "Oh! Susanna" are based on the major pentatonic scale[1] *Play* .

Pentatonic scale in Ravel's Ma Mère l'Oye *III. "Laideronnette, Impératrice des Pagodes", m.9-13.*[1] *Play Presumably D♯ minor pentatonic.*

Pentatonic scale in Debussy's Voiles, *Preludes, Book I, no. 2, mm.43-45.*[2] *Play*

32.1 Pervasiveness

Pentatonic scales occur in Celtic folk music, German folk music, Nordic folk music, Hungarian folk music, West African music, African-American spirituals, Gospel music, Bluegrass music, American folk music, Jazz, American blues music, rock music, Sami joik singing, children's song, the music of ancient Greece[3][4] and the Greek traditional music and songs from Epirus, Northwest Greece, music of Southern Albania, folk songs of peoples of the Middle Volga area (such as the Mari, the Chuvash and Tatars), the tuning of the Ethiopian krar and the Indonesian gamelan, Philippine kulintang, Native American music, melodies of China, Korea, Laos, Thailand, Malaysia, Japan, and Vietnam (including the folk music of these countries), the Andean music, the Afro-Caribbean tradition, Polish highlanders from the Tatra Mountains, and Western Impressionistic composers such as French composer Claude Debussy. Examples of its use include Chopin's Etude in G-flat major, op. 10, no. 5, the "Black Key" etude,[1] in the major pentatonic.

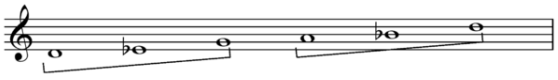
32.2 Types of pentatonic scales

32.2.1 Hemitonic and anhemitonic

Main article: Anhemitonic scale

Ethnomusicology commonly classifies pentatonic scales as either *hemitonic* or *anhemitonic*. Hemitonic scales contain one or more semitones and anhemitonic scales do not contain semitones. For example, in Japanese music the anhemitonic *yo* scale is contrasted with the hemitonic *in* scale. Hemitonic pentatonic scales are also called "ditonic scales", because the largest interval in them is the ditone (e.g., in the scale C–E–F–G–B–C, the interval found between C–E and G–B).[8] This should not be confused with the identical term also used by ethnomusicologists to describe a scale including only two notes.

Minyō *scale on D,*[5] *equivalent to* yo *scale on D,*[6] *with brackets on fourths Play* .



Miyako-bushi *scale on D, equivalent to* in *scale on D, with brackets on fourths*[7] *Play* .

32.2.2 Major pentatonic scale

Anhemitonic pentatonic scales can be constructed in many ways. The major pentatonic scale may be thought of as a gapped or incomplete major scale.[9] However, the pentatonic scale has a unique character and is therefore complete in terms of tonality. One construction takes five consecutive pitches from the circle of fifths;[10] starting on C, these are C, G, D, A, and E. Transposing the pitches to fit into one octave rearranges the pitches into the major pentatonic scale: C, D, E, G, A.

Sorry, your browser either has JavaScript disabled or does not have any supported player.
You can download the clip or download a player to play the clip in your browser.

Another construction works backward: It omits two pitches from a diatonic scale. If we were to begin with a C major scale, for example, we might omit the fourth and the seventh scale degrees, F and B. The remaining notes, C, D, E, G, and A, are transpositionally equivalent to the black keys on a piano keyboard: G-flat, A-flat, B-flat, D-flat, and E-flat.

Sorry, your browser either has JavaScript disabled or does not have any supported player.
You can download the clip or download a player to play the clip in your browser.

Omitting the third and seventh degrees of the C major scale obtains the notes for another transpositionally equivalent anhemitonic pentatonic scale: {F,G,A,C,D}. Omitting the first and fourth degrees of the C major scale gives a third anhemitonic pentatonic scale: {G,A,B,D,E}.

32.2.3 Minor pentatonic scale

Although various hemitonic pentatonic scales might be called *minor*, the term is most commonly applied to the **relative minor pentatonic** derived from the major pentatonic, using scale tones 1, 3, 4, 5, and 7 of the natural minor scale.[1] It may also be considered a gapped blues scale.[11] The C minor pentatonic is C, E-flat, F, G, B-flat. The A minor pentatonic, the relative minor of C, comprises the same tones as the C major pentatonic, starting on A, giving A, C, D, E, G. This minor pentatonic contains all three tones of an A minor triad.

Because of their simplicity, pentatonic scales are often used to introduce children to music.

32.2.4 Five black-key pentatonic scales of the piano

The five pentatonic scales found by running up the black keys on the piano are:

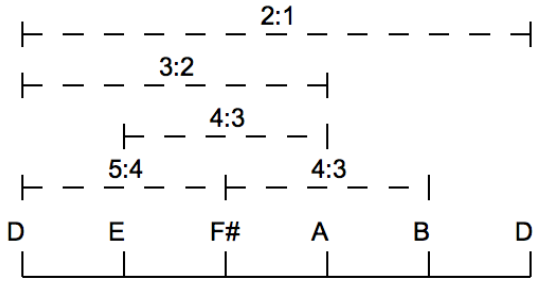
(A minor seventh can be 7:4, 16:9, or 9:5; a major sixth can be 27:16 or 5:3. Both were chosen to minimize ratio parts.)

Ricker assigned the major pentatonic scale mode I while Gilchrist assigned it mode III.[12]

32.3 Pythagorean tuning

Ben Johnston gives the following Pythagorean tuning for the minor pentatonic scale:[13]

Play



Just pentatonic tuning of Lou Harrison's "American gamelan", Old Granddad.[14] This gives the proportions 24:27:30:36:40. Play

Naturals in that table are not the alphabetic series A to G without sharps and flats: Naturals are reciprocals of terms in the Harmonic series (mathematics), which are in practice multiples of a Fundamental frequency. This may be derived by proceeding with the principle that historically gives the Pythagorean diatonic and chromatic scales, stacking perfect fifths with 3:2 frequency proportions (C-G-D-A-E). Considering the anhemitonic scale as a subset of a just diatonic scale, it is tuned thus; 20:24:27:30:36 (A-C-D-E-G = 5/3-1/1-9/8-5/4-3/2). Assigning precise frequency proportions to the pentatonic scales of most cultures is problematic as tuning may be variable.

Slendro approximated in Western notation.[15] Play

For example, the slendro anhemitonic scale and its modes of Java and Bali are said to approach, very roughly, an equally-tempered five note scale,[16] but, in fact, their tunings vary dramatically from gamelan to gamelan.[17]

Specially trained musicians among the Gogo people of Tanzania sing the fourth through ninth (and occasionally tenth) harmonics above a fundamental, which corresponds to the frequency proportions 4:5:6:7:8:9. Up to eight, this is an octaval scale of five notes (8 is the same

note an octave higher as 4), while nine is a major second above eight, and a major ninth above four. The 6:7:8 bit includes two septimal ratios rarely found on western staves (septimal minor third & septimal whole tone).

Composer Lou Harrison has been one of the most recent proponents and developers of new pentatonic scales based on historical models. Harrison and William Colvig tuned the slendro scale of the gamelan Si Betty to overtones 16:19:21:24:28.[18] (1/1-19/16-21/16-3/2-7/4) They tuned the Mills gamelan so that the intervals between scale steps are 8:7-7:6-9:8−8:7-7:6.[19] (1/1-8/7-4/3-3/2-12/7−2/1 = 42:48:56:63:72)

32.4 Further pentatonic musical traditions

The major pentatonic scale is the basic scale of the music of China and the music of Mongolia. The fundamental tones (without *meri* or *kari* techniques) rendered by the 5 holes of the Japanese shakuhachi flute play a minor pentatonic scale. The Yo scale used in Japanese shomyo Buddhist chants and gagaku imperial court music is an anhemitonic pentatonic scale[20] shown below, which is the fourth mode of the major pentatonic scale.

In Javanese gamelan music, the slendro scale is pentatonic, with roughly equally spaced intervals (MIDI sample). Another scale, pelog, has seven tones, but is generally played using one of several pentatonic subsets (known as pathets), which are roughly analogous to different keys or modes.

In Scottish music, the pentatonic scale is very common. The Great Highland bagpipe scale is considered three interlaced pentatonic scales.[21] This is especially true for Piobaireachd which typically uses one of the pentatonic scales out of the nine possible notes. It also features in Irish traditional music, either purely or almost so. The minor pentatonic is used in Appalachian folk music. Blackfoot music most often uses anhemitonic tetratonic or pentatonic scales.[22]

In Andean music, the pentatonic scale is used substantially minor, sometimes major, and seldom *in* scale. In the most ancient genres of Andean music being performed without string instruments (only with winds and percussion), pentatonic melody is often leaded with parallel fifths and fourths, so formally this music is hexatonic. Hear example: Pacha Siku .

Jazz music commonly uses both the major and the minor pentatonic scales. For example, jazz pianists Art Tatum, Chick Corea and Herbie Hancock, blues, and rock. Pentatonic scales are useful for improvisors in modern jazz, pop, and rock contexts because they work well over several chords diatonic to the same key, often better than the parent scale. For example, the blues scale is predominantly derived from the minor pentatonic scale, a very popular scale for improvisation in the realm of blues and rock alike.[23] Rock guitar solo almost all over B minor pentatonic For instance, over a C major triad (C, E, G) in the key of C major, the note F can be perceived as dissonant as it is a half step above the major third (E) of the chord. It is for this reason commonly avoided. Using the major pentatonic scale is an easy way out of this problem. The scale tones 1, 2, 3, 5, 6 (from the major pentatonic) are either major triad tones (1, 3, 5) or common consonant extensions (2, 6) of major triads. For the corresponding relative minor pentatonic, scale tones 1, ♭3, 4, 5, ♭7 work the same way, either as minor triad tones (1, ♭3, 5) or as common extensions (4, ♭7), as they all avoid being a half step from a chord tone.

U.S. military cadences, or “jodies,” which keep soldiers in step while marching or running, also typically use pentatonic scales.[24]

Hymns and other religious music sometimes use the pentatonic scale. For example, the melody of the hymn "Amazing Grace",[25] one of the most famous pieces in religious music.

The common pentatonic major and minor scales (C-D-E-G-A and C-E♭-F-G-B♭, respectively) are useful in modal composing, as both scales allow a melody to be modally ambiguous between their respective major (Ionian, Lydian, Mixolydian) and minor (Aeolian, Phrygian, Dorian) modes (Locrian excluded). With either modal or non-modal writing, however, the *harmonization* of a pentatonic melody does not necessarily have to be derived from only the pentatonic pitches.

32.5 Use in education

The pentatonic scale plays a significant role in music education, particularly in Orff-based, Kodály-based, and Waldorf methodologies at the primary/elementary level. The Orff system places a heavy emphasis on developing creativity through improvisation in children, largely through use of the pentatonic scale. Orff instruments, such as xylophones, bells and other metallophones, use wooden bars, metal bars or bells which can be removed by the teacher leaving only those corresponding to the pentatonic scale, which Carl Orff himself believed to be children’s native tonality.[26] Children begin improvising using only these bars, and over time, more bars are added at the teacher’s discretion until the complete diatonic scale is being used. Orff believed that the use of the pentatonic scale at such a young age was appropriate to the development of each child, since the nature of the scale meant that it was impossible for the child to make any real harmonic mistakes.

In Waldorf education, pentatonic music is considered to be appropriate for young children due to its simplicity and unselfconscious openness of expression. Pentatonic music centered around intervals of the fifth is often sung and

played in early childhood; progressively smaller intervals are emphasized within primarily pentatonic as children progress through the early school years. At around nine years of age the music begins to center around first folk music using a six-tone scale, and then the modern diatonic scales, with the goal of reflecting the children's developmental progress in their musical experience. Pentatonic instruments used include lyres, pentatonic flutes, and tone bars; special instruments have been designed and built for the Waldorf curriculum.[27]

Chapter 33

Heptatonic scale

A **heptatonic scale** is a musical scale with seven pitches per octave. Among the most famous of these are the *major scale*, C D E F G A B C; the *melodic minor scale*, C D E♭ F G A B C ascending, C B♭ A♭ G F E♭ D C descending; the *harmonic minor scale*, C D E♭ F G A♭ B C; and a scale variously known as the Roman *Byzantine*, and *Hungarian*,[1] scale, C D E♭ F♯ G A♭ B C. Indian Classical theory postulates seventy-two seven-tone scale types, whereas others postulate twelve or ten (depending on the theorist) seven-tone scale types collectively called *thaat*.

Several heptatonic scales of Western, Roman, Spanish, Hungarian, and Greek musics can be analyzed as juxtapositions of tetrachords.[2] All heptatonic scales have all intervals present in their interval vector analysis,[3] and thus all heptatonic scales are both hemitonic and tritonic. There is a special affinity for heptatonic scales in the Western key signature system.

33.1 Diatonic scale

Any seven-note scale constructed sequentially using only whole tones and half tones, repeating at the octave, having a tonal center, and comprising only one tritone interval between any two scale members. In Western music, there are seven such scales, and they are commonly known as the modes of the major scale (Ionian, Dorian, Phrygian, Lydian, Mixolydian, Aeolian, and Locrian). However, in Indian Classical music, a theoretical maximum of 72 heptatonic scales are possible though fewer are actually used.

33.2 Melodic minor scale

Melodic minor scale (ascending) on A Play

In traditional classical theory, the melodic minor scale has two forms, as noted above, an ascending form and a descending form. Although each of these forms of itself comprises seven pitches, together they comprise nine, which might seem to call into question the scale's status as a heptatonic scale. In certain twentieth-century music, however, it became common systematically to use the ascending form for both ascending and descending passages. Such a use has been notably ascribed to the works of Béla Bartók and to bop and post-bop jazz practice. The traditional descending form of the melodic minor scale is equivalent to the natural minor scale in both pitch collection (which is diatonic) and tonal center.

33.3 Harmonic minor scale

Harmonic minor scale on A Play

The harmonic minor scale is so called because in tonal music of the common practice period (from approximately 1600 to approximately 1900) chords or harmonies are derived from it more than from the natural minor scale or the melodic minor scale. The augmented second between its sixth degree and its raised seventh degree (the "leading tone"), traditionally considered undesirable in melodic progression, is avoided by placing these pitches in different voices in adjacent chords, as in this progression: F A♭ D, F G B, F A♭ C (ii°$_{\flat}$–V7$_{d}$–iv in C minor). The A♭ in the middle voice does not ascend to B, and the B in the upper voice does not descend to A♭.

33.4 Heptatonia prima and secunda

The names *heptatonia prima* and *heptatonia secunda* are given to the various seven-note scales which can be formed using tones and semitones but without two semitones appearing in succession. Some are more theoretical

than others. They are:

33.4.1 Heptatonia prima

Beginning on keynote A and working up the notes of the 'natural minor' scale (A, B, C, D, E, F, G, A), the seven modes are:

Aeolian mode C Play

- Aeolian mode (natural minor) t-s-t-t-s-t-t

Locrian mode C Play

- Locrian mode s-t-t-s-t-t-t

Ionian mode C Play

- Ionian Mode (major) t-t-s-t-t-t-s

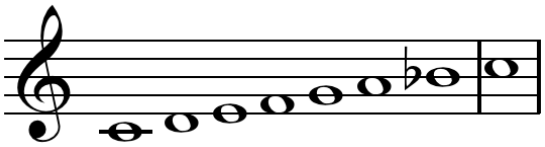
Dorian mode C Play

- Dorian mode t-s-t-t-t-s-t

- Phrygian mode s-t-t-t-s-t-t

Phrygian mode C Play

Lydian mode C Play



Mixolydian mode C. Play

- Lydian mode t-t-t-s-t-t-s

- Mixolydian mode t-t-s-t-t-s-t

The Dorian is exactly the same descending as ascending. The less common series is

33.4.2 Heptatonia secunda

The difference between this and the diatonic modes is that they have two and three tones between each semitone, while these latter modes have one and four. These are sometimes called modes of the melodic ascending minor since that is the most commonly used scale of this type, but other modes can be produced by starting on the different scale notes in turn. Thus starting on keynote A as above and following the notes of the ascending melodic minor (A, B, C, D, E, F♯, G♯) yields these seven modes:

Ascending melodic minor scale on A Play

- 'Melodic ascending minor' t-s-t-t-t-t-s

- 'Phrygian raised sixth' s-t-t-t-t-s-t combines the Phrygian flat second and Dorian raised sixth

- 'Lydian raised fifth' t-t-t-t-s-t-s combines the Lydian fourth with a raised fifth

Acoustic scale on C. Play

- 'Acoustic' or 'Lydian Dominant' Scale t-t-t-s-t-s-t So-called because close to the scale built on natural overtones and combines Lydian raised fourth with Myxolydian (Dominant) flat seventh
- 'Major minor' scale t-t-s-t-s-t-t Like natural minor (aeolian) but with a major third

Half diminished scale on C Play

- 'Half diminished scale' or 'Locrian sharp 2' scale t-s-t-s-t-t-t This is like the Locrian with a raised second

Altered scale on C Play

- 'Altered scale' s-t-s-t-t-t-t Like Locrian with diminished fourth

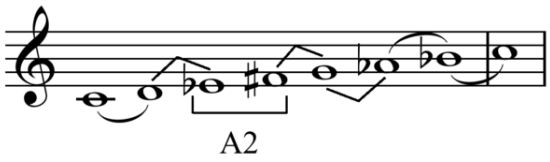
These modes are more awkward to use than those of the diatonic scales due to the four tones in a row yielding augmented intervals on one hand while the one tone between two semitones gives rise to diminished intervals on the other. For example, the last two modes listed above both have 'Locrian' diminished triads built on their tonics, giving them unstable tonality, while the third mode not only has an augmented fourth a la the Lydian mode but also an augmented fifth making the dominant and subdominant unusable.

33.5 Heptatonia tertia

The last group of seven-note tone/semitone scales is known as heptatonia tertia and consists of scales with two adjacent semitones which amounts to a whole-tone scale but with an additional note somewhere in its sequence e.g. B C D E F♯ G♯ A♯.

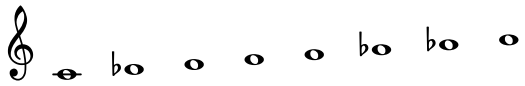
Neapolitan major scale on C Play

33.6 Other heptatonic scales



Hungarian Gypsy scale

If the interval of the augmented second is used, many other scales become possible. These include Gypsy I-bII-III-IV-V-bVI-VII Hungarian I-II-bIII-#IV-V-bVI-VII The scales are symmetrical about the tonic and dominant respectively and the names are sometimes used interchangeably.



Phrygian dominant scale Play

Phrygian major or dominant harmonic minor I-bII-III-IV-V-bVI-bVII This differs from the Phrygian in having a major third. It may also be considered to be built on the dominant of the harmonic minor scale.

Enigmatic scale on C Play

Verdi's Scala Enigmatica I-bII-III-#IV-#V-#VI-VII i.e. G Ab B C♯ D♯ E♯ F♯ which is similar to the heptonia tertia mentioned above, differing only in that the second degree here is flattened.

33.7 Melakarta

Main article: Melakarta

Melakarta is a South Indian Classical method of organizing Raagas based on their unique heptatonic scales.

The postulated number of melakarta derives from arithmetical calculation and not from Carnatic practice, which employs far fewer scale forms. Seven-pitch melakarta are considered subsets of a twelve-pitch scale roughly analogous to the Western chromatic scale. The first and fifth melakarta tones, corresponding to the first and seventh chromatic tones, are invariable in inflection, and the fourth melakarta tone, corresponding to the fifth or sixth chromatic tone, is allowed one of two inflections only, a natural (*shuddah*) position and a raised (*tivra*) position. Thus the number of possible forms is equal to twice the square of the number of ways a two-membered subset can be extracted from a four-membered set:

$$2 \cdot \left(\frac{4!}{2! \cdot 2!} \right)^2 = 2 \cdot 6^2 = 2 \cdot 36 = 72$$

33.8 Thaat

Main article: That (music)

Hindustani heptatonic theory additionally stipulates that the second, third, sixth and seventh degrees of heptatonic scale forms (*septak*) are also allowed only two inflections each, in this case, one natural position, and one lowered (*komal*) position. Arithmetically this produces 2^5, or thirty-two, possibilities, but Hindustani theory, in contradistinction to Carnatic theory, excludes scale forms not commonly used.

33.9 Chinese Gongche notation

Gongche notation heptatonic scale gets a do, re, mi (between fa and fa♯), sol, la (between ti♭ and ti) heptatonic scale.

Chapter 34

Phrygian dominant scale

D Phrygian dominant scale. Play

In music, the **Phrygian dominant scale** is the fifth mode of the harmonic minor scale, the fifth being the dominant.[1] Also called the **altered Phrygian scale**, **harmonic minor perfect fifth below**, **mixolydian flat 9 flat 13** (in jazz), the **Freygish scale** (also spelled Fraigish[2]), or simply the **fifth mode of the harmonic minor scale**, it is constructed by raising the third scale degree of the Phrygian mode.

34.1 Traditional use

It occurs commonly in Middle Eastern, some Eastern European, and Flamenco music. Examples include some versions of "Hava Nagila"[1] and "Misirlou", with other versions of those melodies using the closely related double harmonic scale.[2] "The main chords used with this scale are," I, iv, and vii.[2]

The scale is very common in Middle Eastern music, particularly Arabic and Egyptian music. It is also known as *Ahava Rabbah* or *Freygish* when used in Hebrew prayers and Klezmer music (earning it the additional title of the "Jewish scale"), as the *Hijaz-Nahawand* or *Bayati* maqam when used in Turkish or Arabic music,[3] or as *Bidād* in *Dastgāh-e Homāyoun* in Persian music. In North Indian classical music, this scale corresponds to the raga *Basant Mukhari*. In South Indian classical music, this scale is known as Vakulabharanam.[4]

It is often known as a "Spanish Phrygian scale", "Spanish gypsy scale" (see: gypsy scale) or "Phrygian major scale" (see: phrygian mode and major scale) as it is also commonly used in Flamenco music.[5] The flatted second together with the augmented step between the second and third degrees of the scale create its distinctive mystical, exotic sound.

34.2 Composition

The sequence of steps comprising the Phrygian dominant scale is:

- half – augmented second – half – whole – half – whole – whole

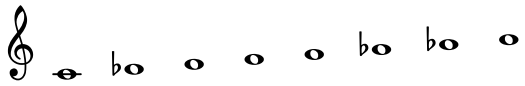
When related to the scale degrees of the major scale, it reads:

1 - ♭2 - 3 - 4 - 5 - ♭6 - ♭7 - 1

Written in semitones, the sequence is:

1312122

Beginning on C, the scale is: C - D♭ - E - F - G - A♭ - B♭ - C



C Phrygian dominant scale, the fifth mode of F harmonic minor Play .

When the Freygish scale is used in Klezmer music, the sixth degree may not be flattened if it is melodically approached and left from above.[6]

34.3 Use in rock

In rock music, the Phrygian dominant scale has been extensively used by guitarists such as Joe Satriani in his instrumental rock compositions such as "Hordes of Locusts" and "Memories", and by Steve Vai in "The Riddle" and his "Fire Garden Suite".

Chapter 35

Hungarian minor scale

Hungarian minor scale on C.[1] *Play*

The **Hungarian minor scale**,[2][3][4][5][6] **Double Harmonic minor scale**,[7] or **Gypsy minor scale**,[4][8] is a type of combined musical scale. It is the fourth mode of the double harmonic scale. It is the same as the harmonic minor scale, except that it has a raised fourth scale degree.[2][3][4][6][7][8] Its tonal center is slightly ambiguous, due to the large number of half steps. Also known as Double Harmonic Minor, or Harmonic Minor ♯4, it figures prominently in Eastern European music, particularly in Romani music. Melodies based on this scale have an exotic, romantic flavor for listeners accustomed to more typical Western scales.

A clear way to see this is the Hungarian Minor scale in the key of A. The notes in this scale would be A B C D♯ E F G♯. In this example the D♯ is the raised 4th and the G♯ is the raised 7th. As a second, more complex example, a Hungarian minor scale in the key of C would proceed as follows: C D E♭ F♯ G A♭ B.

Its step pattern is w - h - + - h - h - + - h, where w indicates a whole step, h indicates a half step, and + indicates an augmented second, which is played as a minor third on a keyboard but is notionally distinct. It may be seen that the scale contains two augmented seconds,[5] one in each tetrachord.[1]

The scale may be used with minor or m+7 chords.[2][6] See: chord-scale system. Chords that may be derived from the A Hungarian Minor scale are Am, B7♭5, C+, E, F7 and G♯m6.
Chords that may be derived from the C Hungarian Minor scale are Cm, D7♭5, E♭+, G, A♭7 and Bm6.[7]

This scale is obtainable from the Arabic scale by starting from the fourth of that scale. Said another way, the C Hungarian minor scale is equivalent to the G Arabic scale.[7]

35.1 Notable recordings

The Pink Panther Theme, originally played in the key of E minor, is noted for its quirky, unusual use of chromaticism which is derived from the scale.[9]

Joe Satriani has composed several songs using the Hungarian minor scale ("Musterion"[10]), and film composer Danny Elfman has frequently used it in his soundtrack work. Oli Herbert of the American Melodic Metalcore band All That Remains uses the Hungarian minor scale in his playing ("Become the Catalyst"[11]).

In Enix's video game *Illusion of Gaia*, the flute melody found in the Inca Ruins uses the C Hungarian minor scale (a ♯4 is used in the second phrase); this music is also quoted in the music of the Larai Cliff stage, transposed to D.

Chapter 36

Persian scale

Persian scale on C Play .

The **Persian scale** is a musical scale occasionally found in guitar scale books, along other scales inspired by Middle Eastern music. It is characterized by the liberal use of half steps (4), augmented seconds (2), and frequent use of chromaticism. Compare this to the one augmented second of the harmonic minor or the use of only two half-steps in all diatonic scales.

The sequence of steps is as follows:[1]

- H WH H H W WH H
- (W = Whole step - H = Half step)

Beginning on C:

- C Db E F Gb Ab B

36.1 See also

- It is most closely related to the Phrygian dominant scale as their bottom tetrachords are identical.[2] It can also be obtained by flattening the fifth degree of the double harmonic scale.

Chapter 37

Lydian augmented scale

Lydian augmented scale on C Play .

In music, the **Lydian augmented scale** (**Lydian ♯5 scale**) is the third mode of the ascending melodic minor scale or jazz minor scale.

Starting on C, the notes would be as follows:

C - D - E - F# - G# - A - B - C'

Generically the whole and half steps are:

- W - W - W - W - H - W - H -

Building on the first scale degree, the scale yields both a Major 7(♯5) chord (C-E-G♯-B) Play and a Major 7(♯11) chord (C-E-G♯-B-F♯).[1] It functions as a I+ Play . See: chord-scale system.

"This scale can be used to create a cool altered major sound."[2] "It has a polychord sound built in,"[2] created by superimposing the Cmaj and the Emaj (Play) and/or F♯dim (Play) triads that exist in the scale, this being "a very common practice for most bop and post-bop players (such as McCoy Tyner)."[3]

The scale may be thought of as a major scale with raised fourth and fifth, or as the relative to the melodic minor ascending scale (C Lydian augmented and A melodic minor ascending share the same notes).

Chapter 38

Aeolian dominant scale

The **Aeolian dominant** scale is the fifth mode of the melodic minor scale (ascending, also known as jazz minor scale). It is named such because its sound derives from having a dominant seventh chord on the tonic in the context of what is otherwise the Aeolian mode, and because it is on the fifth degree of the melodic minor scale. It often goes by other names, such as the Hindu scale, the Mixolydian ♭6, or ♭13, Aeolian major.,[1] and melodic major.[2] The name *melodic major* also refers to the combined scale that goes as natural major ascending and as melodic major descending: C-D-E-F-G-A-B-C-B♭-A♭-G-F-E-D-C (differs from melodic minor only by raising the third degree).[3]

The Mask of Zorro song, *I Want to Spend My Lifetime Loving You*, was composed in the aeolian dominant scale mode. It was written by film composer James Horner.

Chapter 39

Half diminished scale

Half diminished scale on C Play .

The **half diminished scale** is a musical scale more commonly known as "**Locrian ♮2**",[1] name which avoids confusion with the diminished scales (see octatonic scales) and the half-diminished seventh chord (min. 7, flat 5). It may be considered Mode VI, the sixth mode, of the ascending melodic minor scale. See: jazz scale.

On C the scale is associated with dmi7♭5, which functions as a ii^{o} chord in minor. See: chord-scale system.

39.1 Applications

Locrian ♮2 is commonly used in jazz and some rock. It is commonly practiced by such neoclassical metal guitarists as Yngwie Malmsteen and Michael Romeo, and such jazz pianists as Oscar Peterson and Jonah Cristall-Clarke.

The half diminished scales, although derived from classical scales, offer fresh potentials in harmonic and melodic structure.

Chapter 40

Acoustic scale

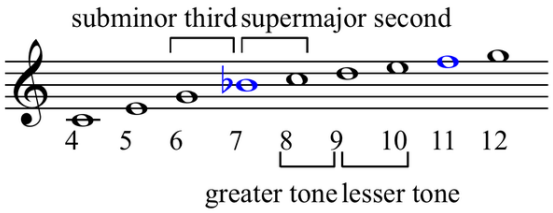
For the concept of scale in acoustics, see Acoustics and Scale (ratio).

In music, the **acoustic scale**, **overtone scale**,[1] **Lydian dominant scale**, or **Lydian ♭7 scale**,[2][3] is a seven-note synthetic scale which, starting on C, contains the notes: C, D, E, F♯, G, A and B♭. This differs from the major scale in having a raised fourth and lowered seventh scale degree. It is the fourth mode of the melodic minor ascending scale.[4][5] The term "acoustic scale" is sometimes used to describe a particular mode of this seven note collection (e.g. the specific ordering C-D-E-F♯-G-A-B♭) and is sometimes used to describe the collection as a whole (e.g. including orderings such as E-F♯-G-A-B♭-C-D).

Acoustic scale on C Play .

The acoustic scale appears sporadically in nineteenth century music, notably in the works of Franz Liszt and Claude Debussy.[6] It also plays a role in the music of twentieth-century composers, including Igor Stravinsky, Béla Bartók,[7] and Karol Szymanowski, who was influenced by folk music from the Polish Highlands.[8] The acoustic scale is also remarkably common in the music of Nordeste, the northeastern region of Brazil[9] (see Escala nordestina). It plays a major role in jazz harmony, where it is used to accompany dominant seventh chords starting on the first scale degree. (That is, the scale C-D-E-F♯-G-A-B♭ is used to accompany the chord C-E-G-B♭. The term "acoustic scale" was coined by Ernő Lendvaï in his analysis of the music of Béla Bartók.[10]

The name "acoustic scale" refers to the resemblance to the eighth through 14th pitch-classes in the harmonic series (Play). Starting on C1, the harmonic series goes C1, C2, G2, C3, E3, G3, B♭3, **C4**, **D4**, **E4**, **F♯4***, **G4**, **A4***, **B♭4***, B4, C5 ... The bold notes spell out an acoustic scale on C4. However, in the harmonic series, the notes marked with asterisks are out of tune; F♯ being almost exactly halfway between F4 and F♯4, A being closer to A♭4 than A4, and B♭ being too flat to be generally accepted relative to equal temperament.



The blue notes (B♭ and F[], 7 and 11) are noticeably out of tune.[11] See: harmonic seventh and eleventh harmonic.

The acoustic scale may have formed from a major triad (C E G) with an added minor seventh and raised fourth (B♭ and F♯, drawn from the overtone series) and major second and major sixth (D and A).[10] Lendvaï described the use of the "acoustic system" accompanying the acoustic scale in Bartók's music, since it entails structural characteristics such as symmetrically balanced sections, especially periods, is contrasted with his use of the golden section. In Bartók's music the acoustic scale is characterized in various ways including diatonic, dynamic, tense, and triple or other odd metered, as opposed to the music structured by the Fibonacci sequence which is chromatic, static, relaxed, and duple metered.[10]

Another way to regard the acoustic scale is that it occurs as a mode of the melodic minor scale, starting on the fourth degree (relative to the minor root), thus being analogous to the Dorian mode. Hence the acoustic scale starting on D is D, E, F♯, G♯, A, B, C, D, containing the familiar sharpened F and G of A melodic minor. The F♯ turns the D minor tetrachord into a major tetrachord, and the G♯ turns it Lydian. Therefore, many occurrences of this scale in jazz may be regarded as unsurprising; it shows up in modal improvisation and composition over harmonic progressions which invite use of the melodic minor.

Chapter 41

Altered scale

In jazz, the **altered scale** or **altered dominant scale** is a seven-note scale that is a dominant scale where all non-essential tones have been altered. An altered scale of C contains the notes: C, D♭, D♯, E, F♯, A♭ and B♭. (This is enharmonically the C Locrian mode, C-D♭-E♭-F-G♭-A♭-B♭, with F changed to F♭. For this reason, the altered scale is sometimes called the "**super Locrian mode**".) It is the seventh mode of the ascending melodic minor scale. The altered scale is also known as the **Pomeroy scale** after Herb Pomeroy (Bahha and Rawlins 2005, 33; Miller 1996, 35), the **Ravel scale** (after Ravel), and the **diminished whole-tone scale** (due to its resemblance to the diminished scale and the whole-tone scale) (Haerle 1975, 15) as well as the **dominant whole-tone scale** and **Locrian flat four** (Service 1993, 28).

The altered scale appears sporadically in the works of Debussy and Ravel (Tymoczko 1997), as well as in the works of recent composers such as Steve Reich (see, in particular, the *Desert Music*). It plays a fundamental role in jazz, where it is used to accompany altered dominant seventh chords starting on the first scale degree. (That is, the scale C-D♭-E♭-F♭-G♭-A♭-B♭ is used to accompany chords such as C-E-G♭-B♭-D♭, the dominant seventh flat five flat nine chord. See: chord-scale system.

The C altered scale consists of the notes C. D♭. E♭. F♭. G♭. A♭. B♭, and C:

C altered scale with flats Play .

One way to obtain the altered scale is by raising the tonic of a major scale by a half step; for example, taking the tonic of the B-major scale, B-C♯-D♯-E-F♯-G♯-A♯-B,

and raising the tonic by a half step produces the scale C-C♯-D♯-E-F♯-G♯-A♯-C,

whose notes are enharmonic (identical, in the equal temperament system) with the notes of the C altered scale.

Like the other modes of the melodic minor ascending or jazz minor scale, the altered scale shares six of its seven notes with an octatonic (or "diminished") scale, and five of the six notes of a whole-tone scale, and thus is occasionally referred to as the "diminished whole tone scale". (For example, the altered scale C-D♭-E♭-F♭-G♭-A♭-B♭ shares all but its A♭ with the octatonic scale C-D♭-E♭-E-F♯-G-A-B♭; while sharing five of the six notes in the whole-tone scale C-D-E-G♭-A♭-B♭.) This accounts for some of its popularity in both the classical and jazz traditions (Callender 1998,; Tymoczko 2004).

B major scale with sharps.

Chapter 42

Mode (music)

This article is about modes as used in music. For other uses, see Mode (disambiguation).

In the theory of Western music, **mode** (from Latin

Modern Dorian mode on C Play

modus, "measure, standard, manner, way, size, limit of quantity, method") (Powers 2001, Introduction; OED) generally refers to a type of scale, coupled with a set of characteristic melodic behaviours. This use, still the most common in recent years, reflects a tradition dating to the Middle Ages, itself inspired by the theory of ancient Greek music.

42.1 Mode as a general concept

Regarding the concept of mode as applied to pitch relationships generally, Harold S. Powers describes a continuum between abstract scale and specific tune, with "most of the area between ... being in the domain of mode" (Powers 2001, §I,3). In this sense the concept had been extrapolated (long before Powers's article) not only to the Western cantus planus monodic tradition but to Byzantine chant (e.g. Wellesz 1954, 41 ff.), and to Russian Znamenny chant (Kholopov 2003, 192) as well. Since the end of the eighteenth century, the term "mode" has also applied to pitch structures in non-European musical cultures, sometimes with doubtful compatibility (Powers 2001, §V,1). The concept is also heavily used in regard to the Western polyphony before advent of the so-called common-practice music, as for example "modale Mehrstimmigkeit" by Carl Dahlhaus (Dalhaus 1968, 174 et passim) or "Tonarten" of the 16th and 17th centuries found by Bernhard Meier (Meier 1974; Meier 1992).

42.2 Additional meanings

The word encompasses several additional meanings, however. Authors from the ninth century until the early eighteenth century (e.g. Guido of Arezzo) sometimes employed the Latin *modus* for interval. In the theory of late-medieval mensural polyphony (e.g. Franco of Cologne), *modus* is a rhythmic relationship between long and short values or a pattern made from them (Powers 2001, Introduction); in mensural music most often theorists applied it to division of longa into 3 or 2 breves.

42.3 Modes and scales

A "scale" is an ordered series of pitches that, with the key or tonic (first tone) as a reference point, defines that scale's intervals, or steps. The concept of "mode" in Western music theory has three successive stages: in Gregorian chant theory, in Renaissance polyphonic theory, and in tonal harmonic music of the common practice period. In all three contexts, "mode" incorporates the idea of the diatonic scale, but differs from it by also involving an element of melody type. This concerns particular repertories of short musical figures or groups of tones within a certain scale so that, depending on the point of view, mode takes on the meaning of either a "particularized scale" or a "generalized tune". Modern musicological practice has extended the concept of mode to earlier musical systems, such as those of Ancient Greek music, Jewish cantillation, and the Byzantine system of *octoechos*, as well as to other non-Western musics (Powers 2001, §I, 3; Winnington-Ingram 1936, 2–3).

By the early 19th century, the word "mode" had taken on an additional meaning, in reference to the difference between major and minor keys, specified as "major mode" and "minor mode". At the same time, composers were beginning to conceive of "modality" as something outside of the major/minor system that could be used to evoke religious feelings or to suggest folk-music idioms (Porter 2001).

42.4 Greek

Early Greek treatises on music do not use the term "mode" (which comes from Latin), but do describe three interrelated concepts that are related to the later, medieval idea of "mode": (1) scales (or "systems"), (2) *tonos*—pl. *tonoi*—(the more usual term used in medieval theory for what later came to be called "mode"), and (3) *harmonia* (harmony)—pl. *harmoniai*—this third term subsuming the corresponding *tonoi* but not necessarily the converse (Mathiesen 2001a, 6(iii)(e)).

42.4.1 Greek scales

Greek Dorian octave species in the enharmonic genus, showing the two component tetrachords Play

Greek Dorian octave species in the chromatic genus Play

Greek Dorian octave species in the diatonic genus Play

The Greek scales in the Aristoxenian tradition were (Barbera 1984, 240; Mathiesen 2001a, 6(iii)(d)):

- Mixolydian: *hypate hypaton–paramese* (b–b′)
- Lydian: *parhypate hypaton–trite diezeugmenon* (c′–c″)
- Phrygian: *lichanos hypaton–paranete diezeugmenon* (d′–d″)
- Dorian: *hypate meson–nete diezeugmenon* (e′–e″)
- Hypolydian: *parhypate meson–trite hyperbolaion* (f′–f″)
- Hypophrygian: *lichanos meson–paranete hyperbolaion* (g′–g″)
- Common, Locrian, or Hypodorian: *mese–nete hyperbolaion* or *proslambnomenos–mese* (a′–a″ or a–a′)

These names are derived from Ancient Greek subgroups (Dorians), one small region in central Greece (Locris), and certain neighboring (non-Greek) peoples from Asia Minor (Lydia, Phrygia). The association of these ethnic names with the octave species appears to precede Aristoxenus, who criticized their application to the *tonoi* by the earlier theorists whom he called the Harmonicists (Mathiesen 2001a, 6(iii)(d)).

Depending on the positioning (spacing) of the interposed tones in the tetrachords, three *genera* of the seven octave species can be recognized. The diatonic genus (composed of tones and semitones), the chromatic genus (semitones and a minor third), and the enharmonic genus (with a major third and two quarter tones or dieses) (Cleonides 1965, 35–36). The framing interval of the perfect fourth is fixed, while the two internal pitches are movable. Within the basic forms, the intervals of the chromatic and diatonic genera were varied further by three and two "shades" (*chroai*), respectively (Cleonides 1965, 39–40; Mathiesen 2001a, 6(iii)(c)).

In contrast to the medieval modal system, these scales and their related *tonoi* and *harmoniai* appear to have had no hierarchical relationships amongst the notes that could establish contrasting points of tension and rest, although the *mese* ("middle note") may have had some sort of gravitational function (Palisca 2006, 77).

42.4.2 *Tonoi*

The term *tonos* (pl. *tonoi*) was used in four senses: "as note, interval, region of the voice, and pitch. We use it of the region of the voice whenever we speak of Dorian, or Phrygian, or Lydian, or any of the other tones" (Cleonides 1965, 44). Cleonides attributes thirteen *tonoi* to Aristoxenus, which represent a progressive transposition of the entire system (or scale) by semitone over the range of an octave between the Hypodorian and the Hypermixolydian (Mathiesen 2001a, 6(iii)(e)). Aristoxenus's transpositional *tonoi*, according to Cleonides (1965, 44), were named analogously to the octave species, supplemented with new terms to raise the number of degrees from seven to thirteen. However, according to the interpretation of at least two modern authorities, in these transpositional *tonoi* the Hypodorian is the lowest, and the Mixolydian next-to-highest—the reverse of the case of the octave species (Mathiesen 2001a, 6(iii)(e); Solomon 1984, 244–45), with nominal base pitches as follows (descending order):

- f: Hypermixolydian (or Hyperphrygian)
- e: High Mixolydian or Hyperiastian
- e♭: Low Mixolydian or Hyperdorian
- d: Lydian
- c♯: Low Lydian or Aeolian

- c: Phrygian
- B: Low Phrygian or Iastian
- B♭: Dorian
- A: Hypolydian
- G♯: Low Hypolydian or Hypoaelion
- G: Hypophrygian
- F♯: Low Hypophrygian or Hypoiastian
- F: Hypodorian

Ptolemy, in his *Harmonics*, ii.3–11, construed the *tonoi* differently, presenting all seven octave species within a fixed octave, through chromatic inflection of the scale degrees (comparable to the modern conception of building all seven modal scales on a single tonic). In Ptolemy's system, therefore there are only seven *tonoi* (Mathiesen 2001a, 6(iii)(e); Mathiesen 2001c). Pythagoras also construed the intervals arithmetically (if somewhat more rigorously, initially allowing for 1:1 = Unison, 2:1 = Octave, 3:2 = Fifth, 4:3 = Fourth and 5:4 = Major Third within the octave). In their diatonic genus, these *tonoi* and corresponding *harmoniai* correspond with the intervals of the familiar modern major and minor scales. See Pythagorean tuning and Pythagorean interval.

42.4.3 *Harmoniai*

In music theory the Greek word *harmonia* can signify the enharmonic genus of tetrachord, the seven octave species, or a style of music associated with one of the ethnic types or the *tonoi* named by them (Mathiesen 2001b).

Particularly in the earliest surviving writings, *harmonia* is regarded not as a scale, but as the epitome of the stylised singing of a particular district or people or occupation (Winnington-Ingram 1936, 3). When the late 6th-century poet Lasus of Hermione referred to the Aeolian *harmonia*, for example, he was more likely thinking of a melodic style characteristic of Greeks speaking the Aeolic dialect than of a scale pattern (Anderson and Mathiesen 2001). By the late fifth century BC these regional types are being described in terms of differences in what is called *harmonia*—a word with several senses, but here referring to the pattern of intervals between the notes sounded by the strings of a lyra or a kithara. However, there is no reason to suppose that, at this time, these tuning patterns stood in any straightforward and organised relations to one another. It was only around the year 400 that attempts were made by a group of theorists known as the harmonicists to bring these *harmoniai* into a single system, and to express them as orderly transformations of a single structure. Eratocles was the most prominent of the harmonicists, though his ideas are known only at second hand, through Aristoxenus, from whom we learn they represented the *harmoniai* as cyclic reorderings of a given series of intervals within the octave, producing seven octave species. We also learn that Eratocles confined his descriptions to the enharmonic genus (Baker 1984–89, 2:14–15).

In *The Republic*, Plato uses the term inclusively to encompass a particular type of scale, range and register, characteristic rhythmic pattern, textual subject, etc. (Mathiesen 2001a, 6(iii)(e)). He held that playing music in a particular *harmonia* would incline one towards specific behaviors associated with it, and suggested that soldiers should listen to music in Dorian or Phrygian *harmoniai* to help make them stronger, but avoid music in Lydian, Mixolydian or Ionian *harmoniai*, for fear of being softened. Plato believed that a change in the musical modes of the state would cause a wide-scale social revolution (Plato, Rep. III.10–III.12 = 398C–403C)

The philosophical writings of Plato and Aristotle (c. 350 BC) include sections that describe the effect of different *harmoniai* on mood and character formation. For example, Aristotle in the *Politics* (viii:1340a:40–1340b:5):

> But melodies themselves do contain imitations of character. This is perfectly clear, for the *harmoniai* have quite distinct natures from one another, so that those who hear them are differently affected and do not respond in the same way to each. To some, such as the one called Mixolydian, they respond with more grief and anxiety, to others, such as the relaxed *harmoniai*, with more mellowness of mind, and to one another with a special degree of moderation and firmness, Dorian being apparently the only one of the *harmoniai* to have this effect, while Phrygian creates ecstatic excitement. These points have been well expressed by those who have thought deeply about this kind of education; for they cull the evidence for what they say from the facts themselves. (Barker 1984–89, 1:175–76)

Aristotle continues by describing the effects of rhythm, and concludes about the combined effect of rhythm and *harmonia* (viii:1340b:10–13):

> From all this it is clear that music is capable of creating a particular quality of character [ἦθος] in the soul, and if it can do that, it is plain that it should be made use of, and that the young should be educated in it. (Barker 1984–89, 1:176)

The word *ethos* (ἦθος) in this context means "moral character", and Greek ethos theory concerns the ways in which music can convey, foster, and even generate ethical states (Anderson and Mathiesen 2001).

42.4.4 Melos

Some treatises also describe "melic" composition (μελοποιΐα), "the employment of the materials subject to harmonic practice with due regard to the requirements of each of the subjects under consideration" (Cleonides 1965, 35)—which, together with the scales, *tonoi*, and *harmoniai* resemble elements found in medieval modal theory (Mathiesen 2001a, 6(iii)). According to Aristides Quintilianus (*On Music*, i.12), melic composition is subdivided into three classes: dithyrambic, nomic, and tragic. These parallel his three classes of rhythmic composition: systaltic, diastaltic and hesychastic. Each of these broad classes of melic composition may contain various subclasses, such as erotic, comic and panegyric, and any composition might be elevating (diastaltic), depressing (systaltic), or soothing (hesychastic) (Mathiesen 2001a, 4).

According to Mathiesen, music as a performing art was called melos, which in its perfect form (μέλος τέλειον) comprised not only the melody and the text (including its elements of rhythm and diction) but also stylized dance movement. Melic and rhythmic composition (respectively, μελοποιΐα and ῥυθμοποιΐα) were the processes of selecting and applying the various components of melos and rhythm to create a complete work. Aristides Quintilianus:

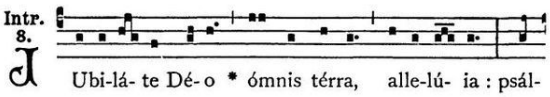
> And we might fairly speak of perfect melos, for it is necessary that melody, rhythm and diction be considered so that the perfection of the song may be produced: in the case of melody, simply a certain sound; in the case of rhythm, a motion of sound; and in the case of diction, the meter. The things contingent to perfect melos are motion-both of sound and body-and also chronoi and the rhythms based on these. (Mathiesen 1983, 75).

42.5 Western Church

Tonaries, which are lists of chant titles grouped by mode, appear in western sources around the turn of the 9th century. The influence of developments in Byzantium, from Jerusalem and Damascus, for instance the works of Saints John of Damascus (d. 749) and Cosmas of Maiouma (Nikodēmos 'Agioreitēs 1836, 1:32–33; Barton 2009), are still not fully understood. The eight-fold division of the Latin modal system, in a four-by-two matrix, was certainly of Eastern provenance, originating probably in Syria or even in Jerusalem, and was transmitted from Byzantine sources to Carolingian practice and theory during the 8th century. However, the earlier Greek model for the Carolingian system was probably ordered like the later Byzantine *oktōēchos*, that is, with the four principal (authentic) modes first, then the four plagals, whereas the Latin modes were always grouped the other way, with the authentics and plagals paired (Powers 2001, §II.1(ii)).

The 6th century scholar Boethius had translated Greek music theory treatises by Nicomachus and Ptolemy into Latin (Powers 2001). Later authors created confusion by applying mode as described by Boethius to explain plainchant modes, which were a wholly different system (Palisca 1984, 222). In his *De institutione musica*, book 4 chapter 15, Boethius, like his Hellenistic sources, twice used the term *harmonia* to describe what would likely correspond to the later notion of "mode", but also used the word "modus"—probably translating the Greek word τρόπος (*tropos*), which he also rendered as Latin *tropus*—in connection with the system of transpositions required to produce seven diatonic octave species (Bower 1984, 253, 260–61), so the term was simply a means of describing transposition and had nothing to do with the church modes (Powers 2001, §II.1(i)).

Later, 9th-century theorists applied Boethius's terms *tropus* and *modus* (along with "tonus") to the system of church modes. The treatise *De Musica* (or *De harmonica institutione*) of Hucbald synthesized the three previously disparate strands of modal theory: chant theory, the Byzantine *oktōēchos* and Boethius's account of Hellenistic theory (Powers 2001, §II.2). The later 9th-century treatise known as the *Alia musica* imposed the seven species of the octave described by Boethius onto the eight church modes (Powers 2001, §II.2(ii)). Thus, the names of the modes used today do not actually reflect those used by the Greeks.



The introit Jubilate Deo*, from which Jubilate Sunday gets its name, is in Mode 8.*

The eight church modes, or Gregorian modes, can be divided into four pairs, where each pair shares the "final" note and the four notes above the final, but have different ambituses, or ranges. If the "scale" is completed by adding three higher notes, the mode is termed *authentic*, if the scale is completed by adding three lower notes, it is called *plagal* (from Greek πλάγιος, "oblique, sideways"). Otherwise explained: if the melody moves mostly above the final, with an occasional cadence to the sub-final, the mode is authentic. Plagal modes shift range and also explore the fourth below the final as well as the fifth above. In both cases, the strict ambitus of the mode is one octave. A melody that remains confined to the mode's ambitus is called "perfect"; if it falls short of it, "imperfect"; if it exceeds it, "superfluous"; and a melody that combines the ambituses of both the plagal and authentic is said to be in a "mixed mode" (Rockstro 1880, 343).

Although the earlier (Greek) model for the Carolingian system was probably ordered like the Byzantine *ok-*

tōēchos, with the four authentic modes first, followed by the four plagals, the earliest extant sources for the Latin system are organized in four pairs of authentic and plagal modes sharing the same final: protus authentic/plagal, deuterus authentic/plagal, tritus authentic/plagal, and tetrardus authentic/plagal (Powers 2001, §II, 1 (ii)).

Each mode has, in addition to its final, a "reciting tone", sometimes called the "dominant" (Apel 1969, 166; Smith 1989, 14). It is also sometimes called the "tenor", from Latin *tenere* "to hold", meaning the tone around which the melody principally centres (Fallows 2001). The reciting tones of all authentic modes began a fifth above the final, with those of the plagal modes a third above. However, the reciting tones of modes 3, 4, and 8 rose one step during the tenth and eleventh centuries with 3 and 8 moving from B to C (half step) and that of 4 moving from G to A (whole step) (Hoppin 1978, 67).

After the reciting tone, every mode is distinguished by scale degrees called "mediant" and "participant". The mediant is named from its position between the final and reciting tone. In the authentic modes it is the third of the scale, unless that note should happen to be B, in which case C substitutes for it. In the plagal modes, its position is somewhat irregular. The participant is an auxiliary note, generally adjacent to the mediant in authentic modes and, in the plagal forms, coincident with the reciting tone of the corresponding authentic mode (some modes have a second participant) (Rockstro 1880, 342).

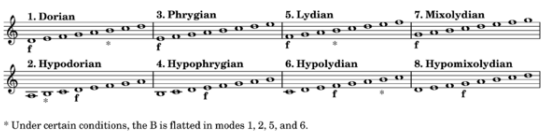
Only one accidental is used commonly in Gregorian chant—B may be lowered by a half-step to B♭. This usually (but not always) occurs in modes V and VI, as well as in the upper tetrachord of IV, and is optional in other modes except III, VII and VIII (Powers 2001, §II.3.i(b), Ex. 5).

Kyrie "orbis factor", in mode 1 (Dorian) with B♭ on scale-degree 6, descends from the reciting tone, A, to the final, D, and uses the subtonium (tone below the final).

In 1547, the Swiss theorist Henricus Glareanus published the *Dodecachordon*, in which he solidified the concept of the church modes, and added four additional modes: the Aeolian (mode 9), Hypoaeolian (mode 10), Ionian (mode 11), and Hypoionian (mode 12). A little later in the century, the Italian Gioseffo Zarlino at first adopted Glarean's system in 1558, but later (1571 and 1573) revised the numbering and naming conventions in a manner he deemed more logical, resulting in the widespread promulgation of two conflicting systems. Zarlino's system reassigned the six pairs of authentic–plagal mode numbers to finals in the order of the natural hexachord, C D E F G A, and transferred the Greek names as well, so that modes 1 through 8 now became C-authentic to F-plagal, and were now called by the names Dorian to Hypomixolydian. The pair of G modes were numbered 9 and 10 and were named Ionian and Hypoionian, while the pair of A modes retained both the numbers and names (11, Aeolian, and 12 Hypoaeolian) of Glarean's system. While Zarlino's system became popular in France, Italian composers preferred Glarean's scheme because it retained the traditional eight modes, while expanding them. Luzzasco Luzzaschi was an exception in Italy, in that he used Zarlino's new system (Powers 2001, §III.4(ii)(a), (iii) & §III.5(i & ii)).

In the late-eighteenth and nineteenth centuries, some chant reformers (notably the editors of the Mechlin, Pustet-Ratisbon (Regensburg), and Rheims-Cambrai Office-Books, collectively referred to as the Cecilian Movement) renumbered the modes once again, this time retaining the original eight mode numbers and Glareanus's modes 9 and 10, but assigning numbers 11 and 12 to the modes on the final B, which they named Locrian and Hypolocrian (even while rejecting their use in chant). The Ionian and Hypoionian modes (on C) become in this system modes 13 and 14 (Rockstro 1880, 342).

Given the confusion between ancient, medieval, and modern terminology, "today it is more consistent and practical to use the traditional designation of the modes with numbers one to eight" (Curtis 1997), using Roman numeral (I–VIII), rather than using the pseudo-Greek naming system. Contemporary terms, also used by scholars, are simply the Greek ordinals ("first", "second", etc.), usually transliterated into the Latin alphabet: protus (πρῶτος), deuterus (δεύτερος), tritus (τρίτος), and tetrardus (τέταρτος), in practice used as: protus authentus / plagalis.



*The eight musical modes. **f** indicates "final" (Curtis 1997,).*

42.5.1 Use

A mode indicated a primary pitch (a final); the organization of pitches in relation to the final; suggested range; melodic formulas associated with different modes; location and importance of cadences; and affect (i.e., emotional effect/character). Liane Curtis writes that "Modes should not be equated with scales: principles of melodic organization, placement of cadences, and emotional affect are essential parts of modal content" in Medieval and Renaissance music (Curtis 1997, in Knighton 1997).

Carl Dahlhaus (1990, 192) lists "three factors that form the respective starting points for the modal theories of Aurelian of Réôme, Hermannus Contractus, and Guido of Arezzo:

- the relation of modal formulas to the comprehensive system of tonal relationships embodied in the diatonic scale;
- the partitioning of the octave into a modal framework; and
- the function of the modal final as a relational center."

The oldest medieval treatise regarding modes is *Musica disciplina* by Aurelian of Réôme (dating from around 850) while Hermannus Contractus was the first to define modes as partitionings of the octave (Dahlhaus 1990, 192–91). However, the earliest Western source using the system of eight modes is the Tonary of St Riquier, dated between about 795 and 800 (Powers 2001).

Various interpretations of the "character" imparted by the different modes have been suggested. Three such interpretations, from Guido of Arezzo (995–1050), Adam of Fulda (1445–1505), and Juan de Espinosa Medrano (1632–1688), follow:

42.6 Modern

The modern Western modes consist of seven scales related to the familiar major and minor keys.

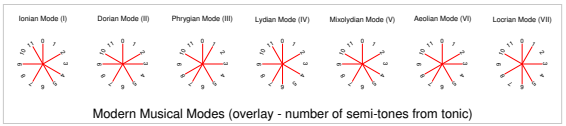
Although the names of the modern modes are Greek and some have names used in ancient Greek theory for some of the *harmoniai*, the names of the modern modes are conventional and do not indicate a link between them and ancient Greek theory, and they do not present the sequences of intervals found even in the diatonic genus of the Greek octave species sharing the same name.

Modern Western modes use the same set of notes as the major scale, in the same order, but starting from one of its seven degrees in turn as a "tonic", and so present a different sequence of whole and half steps. The interval sequence of the major scale being T-T-s-T-T-T-s, where "s" means a semitone and "T" means a whole tone, it is thus possible to generate the following scales:

For the sake of simplicity, the examples shown above are formed by natural notes (also called "white-notes", as they can be played using the white keys of a piano keyboard). However, any transposition of each of these scales is a valid example of the corresponding mode. In other words, transposition preserves mode.

42.6.1 Analysis

Each mode has characteristic intervals and chords that give it its distinctive sound. The following is an analysis



Pitch constellations of the modern musical modes

of each of the seven modern modes. The examples are provided in a key signature with no sharps or flats (scales composed of natural notes).

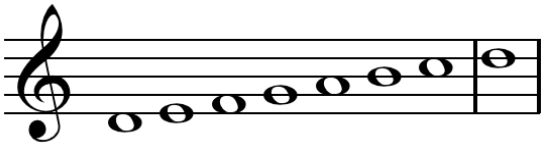
Ionian (I)

Ionian mode on C Play

Ionian may arbitrarily be designated the first mode. It is the modern major scale. The example composed of natural notes begins on C, and is also known as the C-major scale:

- Tonic triad: C
- Tonic seventh chord: CM7
- Dominant triad: G (in modern tonal thinking, the fifth or dominant scale degree, which in this case is G, is the next-most important chord root after the tonic)
- Seventh chord on the dominant: G7 (a "dominant 7th" chord type, so-called because of its position in this—and only this—modal scale)
- The major-minor 7th chord ("dominant 7th" type chord) occurs on V, the one mode where the major-minor 7th is actually a dominant 7th chord.

Dorian (II)



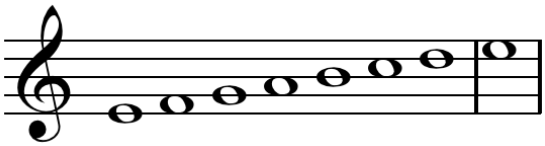
Dorian mode on D Play

Dorian is the second mode. The example composed of natural notes begins on D:

The Dorian mode is very similar to the modern natural minor scale (see Aeolian mode below). The only difference with respect to the natural minor scale is in the sixth scale degree, which is a major sixth (M6) above the tonic, rather than a minor sixth (m6).

- Tonic triad: Dm
- Tonic seventh chord: Dm7
- Dominant triad: Am
- Seventh chord on the dominant: Am7 (a "minor seventh" chord type).
- The major-minor 7th chord (“dominant 7th” type chord) occurs on IV.

Phrygian (III)



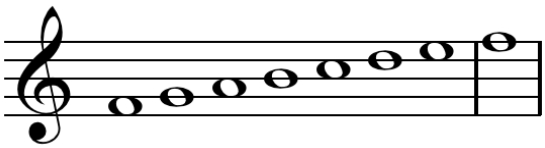
Phrygian mode on E Play

Phrygian is the third mode. The example composed of natural notes starts on E:

The Phrygian mode is very similar to the modern natural minor scale (see Aeolian mode below). The only difference with respect to the natural minor scale is in the second scale degree, which is a minor second (m2) above the tonic, rather than a major second (M2).

- Tonic triad: Em
- Tonic seventh chord: Em7
- Dominant triad: Bdim
- Seventh chord on the dominant: Bø, a "half-diminished seventh" chord type.
- The major-minor 7th chord (“dominant 7th” type chord) occurs on III.

Lydian (IV)



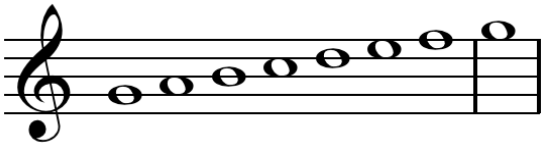
Lydian mode on F Play

Lydian is the fourth mode. The example composed of natural notes starts on F:

The single tone that differentiates this scale from the major scale (Ionian mode), is its fourth degree, which is an augmented fourth (A4) above the tonic (F), rather than a perfect fourth (P4).

- Tonic triad: F
- Tonic seventh chord: FM7
- Dominant triad: C
- Seventh chord on the dominant: CM7, a "major-seventh" chord type.
- The major-minor 7th chord (“dominant 7th” type chord) occurs on II.

Mixolydian (V)



Mixolydian mode on G Play

Mixolydian is the fifth mode. The example composed of natural notes begins on G:

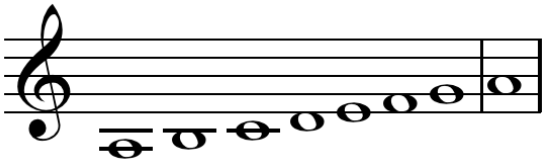
The single tone that differentiates this scale from the major scale (Ionian mode), is its seventh degree, which is a minor seventh (m7) above the tonic (G), rather than a major seventh (M7).

- Tonic triad: G
- Tonic seventh chord: G7 (the “dominant-seventh” chord *type* in this mode is the seventh chord built on the tonic degree)
- Dominant triad: Dm
- Seventh chord on the dominant: Dm7, a “minor-seventh” chord type.
- The major-minor 7th chord (“dominant 7th” type chord) occurs on I.

Aeolian (VI)

Aeolian is the sixth mode. It is also called the natural minor scale. The example composed of natural notes begins on A, and is also known as the A-minor scale:

- Tonic triad: Am



Aeolian mode on A Play

- Tonic seventh chord: Am7
- Dominant triad: Em
- Seventh chord on the dominant: Em7, a "minor-seventh" chord type.
- The major-minor 7th chord ("dominant 7th" type chord) occurs on VII.

Locrian (VII)

Locrian mode on B Play

Locrian is the seventh and final mode. The example composed of natural notes begins on B:

The distinctive scale degree here is the diminished fifth (d5). This makes the tonic triad diminished, so this mode is the only one in which the chords built on the tonic and dominant scale degrees have their roots separated by a diminished, rather than perfect, fifth. Similarly the tonic seventh chord is half-diminished.

- Tonic triad: Bdim or B°
- Tonic seventh chord: Bm7♭5 or Bø
- Dominant triad: FM
- Seventh chord on the dominant: FM7, a major-seventh chord type.
- The major-minor 7th chord ("dominant 7th" type chord) occurs on VI.

42.6.2 Summary

The modes can be arranged in the following sequence, which follows the circle of fifths. In this sequence, each mode has one more lowered interval relative to the tonic than the mode preceding it. Thus taking Lydian as reference, Ionian (major) has a lowered fourth; Mixolydian, a lowered fourth and seventh; Dorian, a lowered fourth, seventh, and third; Aeolian (Natural Minor), a lowered fourth, seventh, third, and sixth; Phrygian, a lowered fourth, seventh, third, sixth, and second; and Locrian, a lowered fourth, seventh, third, sixth, second, and fifth. Put another way, the augmented fourth of the Lydian scale has been reduced to a perfect fourth in Ionian, the major seventh in Ionian, to a minor seventh in Mixolydian, etc.

The tonic of a transposed mode is at the same number of 5ths down (resp. up) from the natural tonic of the mode as there are flats (resp. sharps) in its signature: e.g. the Dorian scale with 3 ♭ is F dorian as F is three 5ths down from D (F - C - G - D) and the Dorian scale with 3 ♯ is B dorian as B is three 5ths up from D (D - A - E - B). Or equivalently it is at the same interval from the tonic of the major scale with the same signature (its relative major) as that formed by its natural tonic and C: e.g. the Lydian scale with 2 ♭ is E♭ Lydian and the Lydian scale with 2 ♯ is G Lydian as E♭ forms with B♭ (relative major) and G forms with D (relative major), the same interval as between F and C.

Conversely the signature of a transposed mode has as many sharps (resp. flats) as there are 5ths up (resp. down) between the tonic of the natural mode and the tonic of the transposed mode: e.g. B♭ Dorian's signature is 4 ♭ as B♭ is four 5ths down from D (B♭ - F - C - G - D) and A lydian's signature is 4 ♯ as A is four 5ths up from F (F - C - G - D - A). Or again equivalently the signature of a transposed mode is the same as that of its relative major. That forms with the tonic of the transposed mode the same interval as C with the tonic of the natural mode: e.g. B♭ Phrygian's signature is 6 ♭ as its relative major is G♭ (C is a major 3rd down from E) and C♯ Mixolydian's signature is 6 ♯ as its relative major is F♯ (C is a 5th down from G).

For example the modes transposed to a common tonic of C have the following signatures:

The first three modes are sometimes called major, the next three minor, and the last one diminished (Locrian), according to the quality of their tonic triads.

The Locrian mode is traditionally considered theoretical rather than practical because the triad built on the first scale degree is diminished. Diminished triads are not consonant and therefore do not lend themselves to cadential endings. A diminished chord cannot be tonicized according to tonal phrasing practice.

Major modes

The Ionian mode (listen) corresponds to the major scale. Scales in the Lydian mode (listen) are major scales with the fourth degree raised a semitone. The Mixolydian mode (listen) corresponds to the major scale with the seventh degree lowered a semitone.

Minor modes

The Aeolian mode (listen) is identical to the natural minor scale. The Dorian mode (listen) corresponds to the natural minor scale with the sixth degree raised a semitone. The Phrygian mode (listen) corresponds to the natural minor scale with the second degree lowered a semitone.

Diminished mode

The Locrian (listen) is neither a major nor a minor mode because, although its third scale degree is minor, the fifth degree is diminished instead of perfect. For this reason it is sometimes called a "diminished" scale, though in jazz theory this term is also applied to the octatonic scale. This interval is enharmonically equivalent to the augmented fourth found between scale-degrees 1 and 4 in the Lydian mode and is also referred to as the tritone.

42.6.3 Use

Use and conception of modes or modality today is different from that in early music. As Jim Samson explains, "Clearly any comparison of medieval and modern modality would recognize that the latter takes place against a background of some three centuries of harmonic tonality, permitting, and in the nineteenth century requiring, a dialogue between modal and diatonic procedure" (Samson 1977, 148). Indeed, when 19th-century composers revived the modes, they rendered them more strictly than Renaissance composers had, to make their qualities distinct from the prevailing major-minor system. Renaissance composers routinely sharped leading tones at cadences and lowered the fourth in the Lydian mode (Carver 2005, 74n4).

The Ionian, or Iastian (Anon. 1896; Chafe 1992, 23, 41, 43, 48; Glareanus 1965, 153; Hiley 2002, §2(b); Powers 2001, §4.ii(a); Pratt 1907, 67; Taylor 1876, 419; Wiering 1995, 25) mode is another name for the major scale used in much Western music. The Aeolian forms the base of the most common Western minor scale; in modern practice the Aeolian mode is differentiated from the minor by using only the seven notes of the Aeolian scale. By contrast, minor mode compositions of the common practice period frequently raise the seventh scale degree by a semitone to strengthen the cadences, and in conjunction also raise the sixth scale degree by a semitone to avoid the awkward interval of an augmented second. This is particularly true of vocal music (Jones 1974, 33).

Traditional folk music provides countless examples of modal melodies. For example, Irish traditional music makes extensive usage not only of the major mode, but also the Mixolydian, Dorian, and Aeolian modes (Cooper 1995, 9–20). Much Flamenco music is in the Phrygian mode.

Zoltán Kodály, Gustav Holst, Manuel de Falla use modal elements as modifications of a diatonic background, while in the music of Debussy and Béla Bartók modality replaces diatonic tonality (Samson 1977,)

42.7 Other types

While the term "mode" is still most commonly understood to refer to Ionian, Dorian, Phrygian, Lydian, Mixolydian, Aeolian, or Locrian scales, in modern music theory the word is sometimes applied to scales other than the diatonic. This is seen, for example, in "melodic minor" scale harmony, which is based on the seven rotations of the ascending melodic minor scale, yielding some interesting scales as shown below. The "chord" row lists tetrads that can be built from the pitches in the given mode (Levine 1995, 55–); see also Avoid note.

The number of possible modes for any intervallic set is dictated by the pattern of intervals in the scale. For scales built of a pattern of intervals that only repeats at the octave (like the diatonic set), the number of modes is equal to the number of notes in the scale. Scales with a recurring interval pattern smaller than an octave, however, have only as many modes as notes within that subdivision: e.g., the diminished scale, which is built of alternating whole and half steps, has only two distinct modes, since all odd-numbered modes are equivalent to the first (starting with a whole step) and all even-numbered modes are equivalent to the second (starting with a half step). The chromatic and whole-tone scales, each containing only steps of uniform size, have only a single mode each, as any rotation of the sequence results in the same sequence. Another general definition excludes these equal-division scales, and defines modal scales as subsets of them: "If we leave out certain steps of a[n equal-step] scale we get a modal construction" (Karlheinz Stockhausen, in Cott 1973, 101). In "Messiaen's narrow sense, *a mode is any scale* made up from the 'chromatic total,' the twelve tones of the tempered system" (Vieru 1985, 63).

Chapter 43

Dorian mode

Modern Dorian scale on C Play .

Dorian mode or **Doric mode** can refer to three very different but interrelated subjects: one of the Ancient Greek *harmoniai* (characteristic melodic behaviour, or the scale structure associated with it), one of the medieval musical modes, or, most commonly, one of the modern modal diatonic scales, corresponding to the white notes from D to D, or any transposition of this, for example the scale from C to C with both E and B flatted.

43.1 Greek Dorian mode

Greek Dorian mode (enharmonic genus) on E, divided into two tetrachords. Play

Greek Dorian mode (chromatic genus) on E. Play

Greek Dorian mode (diatonic genus) on E Play .

The Dorian mode (properly *harmonia* or *tonos*) is named after the Dorian Greeks. Applied to a whole octave, the Dorian octave species was built upon two tetrachords (four-note segments) separated by a whole tone, running from the *hypate meson* to the *nete diezeugmenon*. In the enharmonic genus, the intervals in each tetrachord are quarter-tone–quarter-tone–major third; in the chromatic genus, semitone-semitone-minor third; in the diatonic genus, semitone-tone-tone. In the diatonic genus, the sequence over the octave is the same as that produced by playing all the white notes of a piano ascending from E to E: E F G A | B C D E,[1] a sequence equivalent to the modern Phrygian mode. Placing the single tone at the bottom of the scale followed by two conjunct tetrachords (that is, the top note of the first tetrachord is also the bottom note of the second), produces the Hypodorian ("below Dorian") octave species: A | B C D E | (E) F G A. Placing the two tetrachords together and the single tone at the top of the scale produces the Mixolydian octave species, a note sequence equivalent to modern Locrian mode.[2]

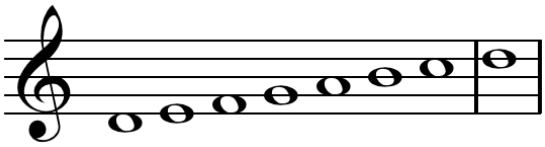
43.2 Medieval and modern Dorian mode

43.2.1 Medieval Dorian mode

The early Byzantine church developed a system of eight musical modes (the octoechoi), which served as a model for medieval European chant theorists when they developed their own modal classification system starting in the 9th century.[3] The success of the Western synthesis of this system with elements from the fourth book of *De institutione musica* of Boethius, created the false impression that the Byzantine oktōēchos were inherited directly from ancient Greece.[4] Originally used to designate one of the traditional *harmoniai* of Greek theory (a term with various meanings, including the sense of an octave consisting of eight tones), the name was appropriated (along with six others) by the 2nd-century theorist Ptolemy to designate his seven *tonoi*, or transposition keys. Four centuries later, Boethius interpreted Ptolemy in Latin, still with the meaning of transposition keys, not scales. When chant theory was first being formulated in the 9th century, these seven names plus an eighth, Hypermixolydian (later changed to Hypomixolydian), were again re-appropriated

in the anonymous treatise *Alia Musica*. A commentary on that treatise, called the *Nova expositio*, first gave it a new sense as one of a set of eight diatonic species of the octave, or scales. In medieval theory, the authentic Dorian mode could include the note B♭ "by licence", in addition to B♮.[5] The same scalar pattern, but starting a fourth or fifth below the mode final D, and extending a fifth above (or a sixth, terminating on B♭), was numbered as mode 2 in the medieval system. This was the plagal mode corresponding to the authentic Dorian, and was called the Hypodorian mode.[6] In the untransposed form on D, in both the authentic and plagal forms the note C is often raised to C♯ to form a leading tone, and the variable sixth step is in general B♮ in ascending lines and B♭ in descent.[7]

43.2.2 Modern Dorian mode



Modern Dorian scale on D Play .

Dorian mode in Ernest Bloch's Chanty *from* Poems of the Sea, *mm. 1-8.*[8] *Play*

The modern Dorian mode (also called **Russian minor** by Balakirev[9]), by contrast, is a strictly diatonic scale corresponding to the white keys of the piano from "D" to "D", or any transposition of its interval pattern, which has the ascending pattern of:

> Whole Step - Half Step - Whole Step - Whole Step - Whole Step - Half Step - Whole Step

or abbreviated:

> W-H-W-W-W-H-W

Alternatively:

> Tone - Semitone - Tone - Tone - Tone - Semitone - Tone

or T-S-T-T-T-S-T.

It can also be thought of as a scale with a minor third and seventh, a major second and sixth, and a perfect fourth and fifth.

It may be considered an "excerpt" of a major scale played from the pitch a whole tone above the major scale's tonic (in the key of C Major it would be D, E, F, G, A, B, C, D), i.e., a major scale played from its second scale degree up to its second degree again. The resulting scale is, however, *minor* in quality, because, as the "D" becomes the new tonal centre, the F a minor third above the D becomes the new mediant, or third degree. If a triad is built upon the tonic, it is a minor triad.

Examples of the Dorian mode include:

- The D Dorian mode, which contains all notes the same as the C major scale starting on D.
- The G Dorian mode, which contains all notes the same as the F major scale starting on G.
- The A♭ Dorian mode, which contains all notes the same as the G♭ major scale starting on A♭.

The Dorian mode is a symmetric scale, meaning that the pattern of whole and half notes (W-H-W-W-W-H-W) is the same ascending or descending.

The modern Dorian mode is equivalent to the natural minor scale (or the Aeolian mode) but with the sixth degree raised a half step. Confusingly, the modern Dorian mode resembles the Greek Phrygian *harmonia* in the diatonic genus. (It should also be noted that the diatonic genus of the Greek Dorian *harmonia* resembles the modern Phrygian mode.)

The only difference between the Dorian and Aeolian scales is whether or not the 6th is major (in the Aeolian it is minor, in the Dorian it is major). The I, IV, and V triads of the Dorian mode are minor, major, and minor, respectively (i-IV-v), instead of all minor (i-iv-v) as in Aeolian. In both the Dorian and Aeolian, strictly applied, the dominant triad is minor, in contrast to the tonal minor scale, where it is normally major (see harmonic minor). It is also worth noting that the sixth scale degree is often raised in minor music, just as it is often lowered in the Dorian mode (see melodic minor). The major subdominant chord gives the Dorian mode a brighter tonality than natural minor; the raised sixth is a tritone away from the minor third of the tonic. The subdominant also has a mixolydian ("dominant") quality.

The Dorian mode is harmonically similar to the ascending melodic minor scale, except for the major seventh degree in minor. This means that the dominant chord is a minor triad in the Dorian but a major one in minor keys. A second harmonic difference is the subdominant chord, which is major in the Dorian mode but minor in minor keys, because of the minor sixth scale degree. It is be-

cause of the similarity that the Dorian is also known as the jazz minor scale.

43.3 Notable compositions in Dorian mode

43.3.1 Traditional

- "Drunken Sailor"[10]
- "Scarborough Fair"[10]

43.3.2 Classical

- The "Et incarnatus est" in the Credo movement of Beethoven's *Missa Solemnis*.[11]

43.3.3 Jazz

- "Maiden Voyage" by Herbie Hancock[12] – The composition takes an AABBA form with the "A" sections in G Dorian and the "B" sections in A Aeolian.[13]
- "Milestones" by Miles Davis[12]
- "Oye Como Va" by Tito Puente, popularized by Santana[14]
- "So What" by Miles Davis[12] - The composition takes an AABA form with the "A" sections in D Dorian and the "B" section in E♭ Dorian.[15]

43.3.4 Popular

- "Eleanor Rigby" by The Beatles[16] is often cited as a Dorian modal piece, and while the melody line is a Dorian melody (excepting some portions), the chord progression is in Aeolian (I–♭VI and ♭VI–I).[17]
- "Paradise" by Coldplay[18]
- "Stairway To Heaven" by Led Zeppelin - (mainly in middle section)[19]
- "Wicked Game by Chris Isaak[20]
- "Uptown Funk" by Bruno Mars

43.4 See also

- Kafi, the name used in Hindustani music for the equivalent scale.
- Kharaharapriya, the name used in Carnatic music for the equivalent scale.

Chapter 44

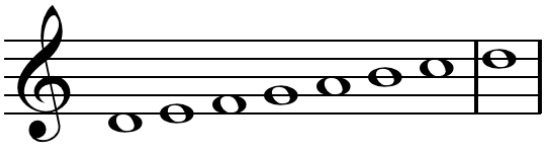
Phrygian mode

Modern Phrygian mode on C Play .

Use of the Phrygian mode on A in Respighi's Trittico Botticelliano *(Botticelli Triptych, 1927).(Benward & Saker 2009), p.244) Play*

The **Phrygian mode** (pronounced /ˈfrɪdʒiən/) can refer to three different musical modes: the ancient Greek *tonos* or *harmonia* sometimes called Phrygian, formed on a particular set of octave species or scales; the Medieval Phrygian mode, and the modern conception of the Phrygian mode as a diatonic scale, based on the latter.

44.1 Ancient Greek Phrygian mode



Diatonic genus of the Phrygian tonos on D Play .

Enharmonic genus of the Phrygian tonos on E (barlines mark the enharmonic tetrachord) Play

The Phrygian *tonos* or *harmonia* is named after the ancient kingdom of Phrygia in Anatolia. The octave species (scale) underlying the ancient-Greek Phrygian *tonos* (in its diatonic genus) corresponds to the medieval and modern Dorian mode.

In Greek music theory, the *harmonia* given this name was based on a *tonos*, in turn based on a scale or octave species built from a tetrachord which, in its diatonic genus, consisted of a series of rising intervals of a whole tone, followed by a semitone, followed by a whole tone (in the chromatic genus, this was a minor third followed by two semitones, and in the enharmonic, a major third and two quarter tones). An octave species was then built upon two of these tetrachords separated by a whole tone. This is equivalent to playing all the white notes on a piano keyboard from D to D:

D E F G | A B C D

This scale, combined with a set of characteristic melodic behaviours and associated ethoi, constituted the *harmonia* which was given the ethnic name "Phrygian", after the "unbounded, ecstatic peoples of the wild, mountainous regions of the Anatolian highlands" (Solomon 1984, 249). This ethnic name was also confusingly applied by theorists such as Cleonides to one of thirteen chromatic transposition levels, regardless of the intervallic makeup of the scale (Solomon 1984, 244–46).

44.2 Medieval Phrygian mode

The early Catholic church developed a system of eight musical modes that medieval music scholars gave names drawn from the ones used to describe the ancient Greek *harmoniai*. The name "Phrygian" was applied to the third of these eight church modes, the authentic mode on E, described as the diatonic octave extending from E to the E an octave higher and divided at B, therefore beginning with a semitone-tone-tone-tone pentachord, followed by a semitone-tone-tone tetrachord (Powers 2001): E F G A B + B C D E

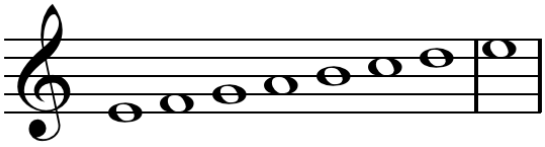
The ambitus of this mode extended one tone lower, to D. The sixth degree, C, which is the tenor of the corresponding third psalm tone, was regarded by most theorists as the most important note after the final, though the fifteenth-century theorist Johannes Tinctoris implied

that the fourth degree, A, could be so regarded instead (Powers 2001).

Placing the two tetrachords together, and the single tone at bottom of the scale produces the Hypophrygian mode (below Phrygian):

G | A B C D | (D) E F G

44.3 Modern Phrygian mode



Modern Phrygian modal scale on E Play .

In modern western music (from the 18th century onward), the Phrygian mode is related to the modern natural minor musical mode, also known as the Aeolian mode: the Phrygian scale differs in its second scale degree, which is a semitone lower than that of the Aeolian.

The following is the Phrygian mode starting on E, or E Phrygian, with corresponding tonal scale degrees illustrating how the modern major mode and natural minor mode can be altered to produce the Phrygian mode:

E Phrygian Mode: E F G A B C D E Major: **1 ♭2 ♭3 4 5 ♭6 ♭7 1** Minor: **1 ♭2 3 4 5 6 7 1**

Therefore, the Phrygian mode consists of: root, minor second, minor third, perfect fourth, perfect fifth, minor sixth, minor seventh, and octave. Alternatively written as a pattern of: Semitone, Tone, Tone, Tone, Semitone, Tone, Tone.

44.4 Modern uses of the Phrygian mode

44.4.1 Phrygian dominant

A Phrygian dominant scale is produced by raising the third scale degree of the mode:

E Phrygian dominant Mode: E F G♯ A B C D E Major: **1 ♭2 3 4 5 ♭6 ♭7 1** Minor: **1 ♭2 ♯3 4 5 6 7 1**

The Phrygian dominant is also known as the **Spanish gypsy scale**, because it resembles the scales found in flamenco music (see Flamenco mode). Flamenco music uses the Phrygian scale, together with a modified scale resembling the Arab *maqām Ḥijāzī* (like the Phrygian dominant but with a major sixth scale degree), and a bimodal configuration using both major and minor second and third scale degrees (Katz 2001).

44.4.2 The Phrygian Mode in Jazz

In contemporary jazz, the Phrygian mode is used over chords and sonorities built on the mode, such as the **sus4(♭9)** chord (see Suspended chord), which is sometimes called a phrygian suspended chord. For example a soloist might play an E Phrygian over an Esus4(♭9) chord (E-A-B-D-F).

44.5 Examples

44.5.1 Ancient Greek

- The First Delphic Hymn, written in 128 BC by the Athenian composer Limenius, is in the Phrygian and Hyperphrygian *tonoi*, with much variation (Pöhlmann and West 2001, 73).
- The Seikilos epitaph (1st century AD) is in the Phrygian species (diatonic genus), in the Iastian (or low Phrygian) transposition (Solomon 1985, 459, 461n14, 470).

44.5.2 Medieval and Renaissance

- The Roman chant variant of the Requiem introit "Rogamus te" is in the (authentic) Phrygian mode, or 3rd tone (Karp, Fitch, and Smallman 2001, §1).
- The following compositions of Josquin are written in the Phrygian mode:
  - 4-part setting of Mille Regretz
  - *Missa Pange lingua*
  - 6-part motet Praeter Rerum Seriem
- Orlando di Lasso's motet *In me transierunt* (Pesic 2005, *passim*).
- Giovanni Pierluigi da Palestrina's motet *Congratulamini mihi* (Carver 2005, 77).
- Cipriano de Rore's 7-part Missa Praeter Rerum Seriem

44.5.3 Baroque

- Johann Sebastian Bach's keeps in his cantatas the Phrygian mode of some original chorale melodies, such as Luther's *Aus tiefer Not schrei ich zu dir* in *Aus tiefer Not schrei ich zu dir, BWV 38*, and *Es woll uns Gott genädig sein* on a melody by Matthaeus Greiter (c. 1490–1552), twice in *Die Himmel erzählen die Ehre Gottes, BWV 76* (Braatz 2006).

- Heinrich Schütz's *St John Passion* (1666) is in the Phrygian mode (Rifkin, Linfield, McCulloch, and Baron 2001, §10)
- Dieterich Buxtehude's Prelude in A minor, BuxWV 152 (Snyder 2001), (labeled *Phrygisch* in the BuxWV catalog) (Karstädt 1985,)

44.5.4 Romantic

- Anton Bruckner:
  - *Ave Regina coelorum* (1885–88) (Carver 2005, 76–77).
  - *Pange lingua* (second setting, 1868), WAB 33 (Carver 2005, 79; Partsch 2007, 227).
  - Symphony no. 3, passages in the third (scherzo) and fourth movements (Carver 2005, 89–90).
  - Symphony no. 4 (third version, 1880), Finale (Carver 2005, 90–92).
  - Symphony no. 6, first, third (scherzo), and fourth movements (Carver 2005, 91–98).
  - Symphony no. 7, first movement (Carver 2005, 96–97).
  - Symphony no. 8, first and fourth movements (Carver 2005, 98).
  - *Tota pulchra es Maria* (1878) (Carver 2005, 79, 81–88).
  - **'Vexilla regis'** (1892) (Carver 2005, 79–80).
- Ralph Vaughan Williams' *Fantasia on a Theme of Thomas Tallis* (Ottaway and Frogley 2001), based on Thomas Tallis's 1567 setting of Psalm 2, "Why fum'th in sight".

44.5.5 Modern

- John Coolidge Adams, *Phrygian Gates* (J. Adams 2010)
- Samuel Barber:
  - *Adagio for Strings*, op. 11 (Pollock 2000, 191)
  - "I Hear an Army", from *Three Songs*, op. 10 (Pollock 2000, 191)
- Philip Glass, the final aria from *Satyagraha* (Strickland 2001).

44.5.6 Popular

- Howard Shore, "Prologue" accompanying the opening sequence of LOTR: The Fellowship of the Ring film (D. Adams 2010, 54).

44.5.7 Jazz

- "Solea" by Gil Evans (Pelletier-Bacquaert n.d.).

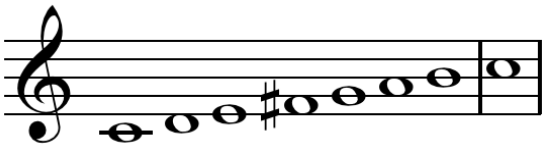
Chapter 45

Lydian mode



Modern Lydian scale on C Play .

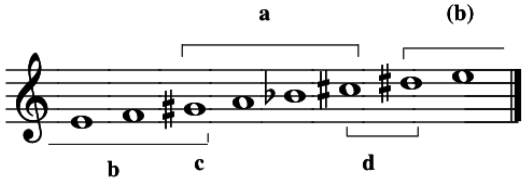
The modern **Lydian** musical scale is a rising pattern of pitches comprising three whole tones, a semitone, two more whole tones, and a final semitone. This sequence of pitches roughly describes the fifth of the eight Gregorian (church) modes, known as Mode V or the authentic mode on F, theoretically using B♮ but in practice more commonly featuring B♭ (Powers 2001). Because of the importance of the major scale in modern music, the Lydian mode is often described (or learned) as the scale that begins on the fourth scale degree of the major scale, or alternatively, as the major scale with the fourth scale degree raised half a step.

45.1 Theory

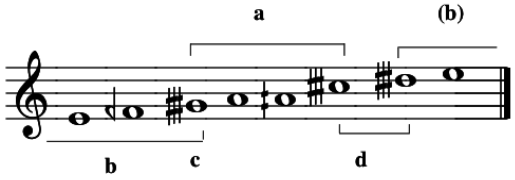
45.1.1 Ancient Greek Lydian

Diatonic genus of the Ancient Greek Lydian scale on C Play .

The name Lydian refers to the ancient kingdom of Lydia in Anatolia. In Greek music theory, there was a Lydian scale or "octave species" extending from *parhypate hypaton* to *trite diezeugmenon*, equivalent in the diatonic genus to the medieval and modern Ionian mode, i.e., the modern major scale: C D E F | G A B C (Barbera 1984, 233, 240). In the chromatic and enharmonic genera, the Lydian scale was equivalent to C D♭ E F G♭ A B C, and C C♯ E♯ F F♯ A♯ B♯ C, respectively (Barker 1984–89, 2:15),

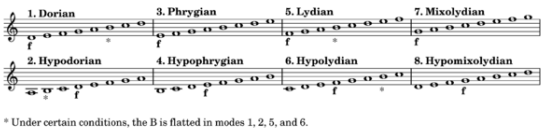


*Ancient Greek Lydian tonos in the chromatic genus, showing tetrachords (*a *and* b*), note of conjunction (*c*) and tone of disjunction (*d*) Play*



*Ancient Greek Lydian tonos in the enharmonic genus, showing tetrachords (*a *and* b*), note of conjunction (*c*) and tone of disjunction (*d*) Play*

where "♯" signifies raising the pitch by approximately a quarter tone.



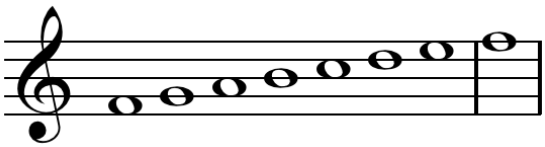
*The eight Gregorian modes: **f** indicates 'final'*

45.1.2 Medieval Lydian mode

In the Middle Ages and Renaissance, this mode was described in two ways. The first way is the diatonic octave species from F up to F an octave above, divided at C to produce two segments: F–G–A–B–C and C–D–E–F. The second is as a mode with a final on F and an ambitus extending to F an octave higher and in which the note C was regarded as having an important melodic function. Many theorists of the period observed that B♭ is used

more typically than B♮ in compositions in Lydian mode (Powers 2001).

45.1.3 Modern Lydian mode



Modern Lydian scale on F Play .

The Lydian scale can be described as a major scale with the fourth scale degree raised a semitone, e.g., a C-major scale with an F♯ rather than F♮.

Triads within Lydian mode

In Lydian mode, the tonic, dominant, and supertonic triads are all major. The subdominant is diminished. The triads built on the remaining three scale degrees are minor.

45.2 Notable compositions in the Lydian mode

45.2.1 Classical (Ancient Greek)

The *Paean and Prosodion to the God*, familiarly known as the Second Delphic Hymn, composed in 128 BC by Athénaios Athenaíou is predominantly in the Lydian *tonos*, both diatonic and chromatic, with sections also in Hypolydian (Pöhlmann and West 2001, 85).

45.2.2 Classical (Modern)

A rare, extended use of the Lydian mode in the Classical repertoire is Simon Sechter's 1822 *Messe in der lydischen Tonart* (Mass in the Lydian Mode) (Carver 2005, 76). A more famous example from around the same time is the third movement of Ludwig van Beethoven's String Quartet No. 15 in A minor, Op. 132 (1825), titled by the composer "Heiliger Dankgesang eines Genesenen an die Gottheit, in der lydischen Tonart" ("Holy Song of Thanksgiving by a Convalescent to the Divinity, in the Lydian Mode"). The alternating passages in F use the Lydian scale with sharp fourth scale degree exclusively. Anton Bruckner employed the sharpened fourth of the Lydian scale in his motet *Os justi* (1879) more strictly than Renaissance composers ever did when writing in this mode (Carver 2005, 74–75). Charles-Valentin Alkan's *Allegro barbaro* (Étude Op. 35, No. 5) is written strictly in F Lydian, with no B♭s present at all (Smith 2000,).

In the 20th century, composers began once again to exploit modal scales with some frequency. An example from the middle of the century is the scherzo movement of Carlos Chávez's Symphony No. 3 (1951–54). The movement opens with a fugue subject, featuring extremely wide leaps, in C Lydian with following entries in F and G Lydian (Orbón 1987, 90–91).

45.2.3 Jazz

Pianist-composer George Russell developed a Lydian Chromatic Concept of Tonal Organization, which became highly influential in the jazz world, inspiring the works of people such as Miles Davis, John Coltrane, Ornette Coleman, and Woody Shaw (Anon. n.d.)

45.2.4 Popular

- *The Simpsons* signature tune (Chase 2006,).
- Passage beginning at the words "Much as I definitely enjoy solitude" in the song "Possibly Maybe" by Björk (Hein 2012).

45.3 See also

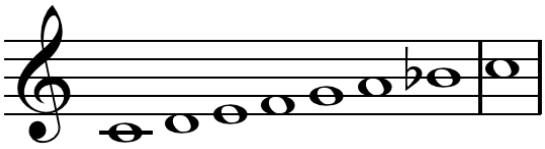
Chapter 46

Mixolydian mode



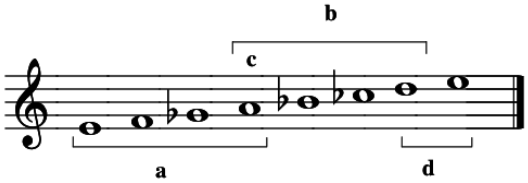
Modern Mixolydian scale on C[1] *Play* .

Mixolydian mode may refer to one of three things: the name applied to one of the ancient Greek *harmoniai* or *tonoi*, based on a particular octave species or scale; one of the medieval church modes; a modern musical mode or diatonic scale, related to the medieval mode. (The Hypomixolydian mode of medieval music, by contrast, has no modern counterpart.)

This mode is known as Harikambhoji in Carnatic music, the classical music form of southern India.

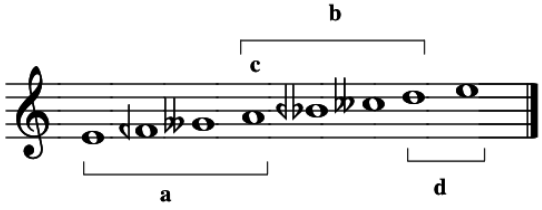
46.1 Greek Mixolydian

Diatonic genus of the Greek Mixolydian scale on B Play .



Chromatic genus of the Greek Mixolydian scale on E: conjunct tetrachords a *and* b*, with note of conjunction* c*, and interval of disjunction* d *Play*

The idea of a Mixolydian mode comes from the music theory of ancient Greece. The ancient Greek Mixolydian mode was invented by Sappho, the 7th century B.C.



Enharmonic genus of the Greek Mixolydian scale on E: conjunct tetrachords a *and* b*, with note of conjunction* c*, and interval of disjunction* d *Play*

poet and musician.[2] However, what the ancient Greeks thought of as Mixolydian was very different from the modern interpretation of the mode.

In Greek theory, the Mixolydian *tonos* (the term "mode" is a later Latin term) employs a scale (or "octave species") corresponding to the Greek Hypolydian mode inverted: in its diatonic genus, this is a scale descending from *paramese* to *hypate hypaton*: in the diatonic genus, a whole tone (*paramese* to *mese*) followed by two conjunct inverted Lydian tetrachords (each being two whole tones followed by a semitone descending). This diatonic genus of the scale is roughly the equivalent of playing all the "white notes" of a piano from B to B, or B | A G F E | (E) D C B, which is also known as modern Locrian mode. (In the chromatic and enharmonic genera, each tetrachord consists of a minor third plus two semitones, and a major third plus two quarter-tones, respectively).[3]

46.2 Medieval Mixolydian and Hypomixolydian

Originally used to designate one of the traditional *harmoniai* of Greek theory, the name was appropriated (along with six others) by the 2nd-century theorist Ptolemy to designate his seven *tonoi*, or transposition keys. Four centuries later, Boethius interpreted Ptolemy in Latin, still with the meaning of transposition keys, not scales. When chant theory was first being formulated in the 9th century, these seven names plus an eighth, Hypermixolydian (later changed to Hypomixolydian), were again re-appropriated

in the anonymous treatise *Alia Musica*. A commentary on that treatise, called the *Nova expositio*, first gave it a new sense as one of a set of eight diatonic species of the octave, or scales.[4] The name *Mixolydian* came to be applied to one of the eight modes of medieval church music: the seventh mode. This mode does not run from B to B on white notes, as the Greek mode, but was defined in two ways: as the diatonic octave species from G up one octave to the G above, or as a mode whose final was G and whose ambitus runs from the F below the final to the G above, with possible extensions "by licence" up to A above and even down to E below, and in which the note D (the tenor of the corresponding seventh psalm tone) had an important melodic function.[5] This medieval theoretical construction led to the modern use of the term for the natural scale from G to G.

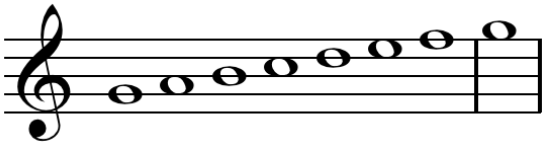
The seventh mode of western church music is an authentic mode based on and encompassing the natural scale from G to G, with the perfect fifth (the D in a G to G scale) as the dominant, reciting note or *tenor*.

The plagal eighth mode was termed Hypomixolydian (or "lower Mixolydian") and, like the Mixolydian, was defined in two ways: as the diatonic octave species from D to the D an octave higher, divided at the mode final, G (thus D–E–F–G + G–A–B–C–D); or as a mode with a final of G and an ambitus from C below the final to E above it, in which the note C (the tenor of the corresponding eighth psalm tone) had an important melodic function.[6]

46.3 Modern Mixolydian

See also: Major scale § Major system

This modern scale has the same series of tones and



Modern Mixolydian scale on G Play .

semitones as the major scale, except the seventh degree is a semitone lower.[1] The Mixolydian mode is sometimes called the **dominant scale**,[7] because it is the mode built on the fifth degree (the dominant) of the major scale. The flattened seventh of the scale is a tritone away from the mediant (major-third degree) of the key.

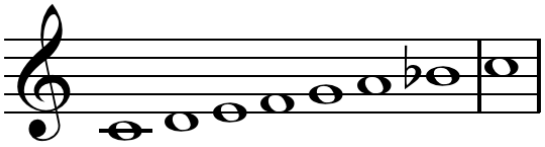
It is common in non-classical harmony, such as jazz, funk, blues and rock music.

The order of tones and semitones in a Mixolydian scale is TTSTTST (T = tone; S = semitone), while the major scale is TTSTTTS. The key signature varies accordingly (it will be the same as that of the major key a fifth below).[1]

Some examples:

- The G Mixolydian mode (Related to the key of C major – on a piano it is all the white keys from one G to the next. GABCDEFG)[1]
- The C Mixolydian mode (Related to the key of F major – CDEFGAB♭C)[1]
- The D Mixolydian mode (Related to the key of G major – DEF♯GABCD)[1]
- The E Mixolydian mode (Related to the key of A major – EF♯G♯ABC♯DE)[1]
- The A Mixolydian mode (Related to the key of D major – scale used on the Great Highland Bagpipes. ABC♯DEF♯GA)

46.4 Moloch scale



Moloch scale on C. Play .

See also: Adonai malakh mode

Moloch scale is the name used by Klezmer musicians for the Mixolydian scale, with which it is identical. In Klezmer, it is usually transposed to C, where the main chords used are C, F, and G7 (sometimes Gm).[8]

46.5 Notable music in Mixolydian mode

46.5.1 Traditional

- "Old Joe Clark"[9][10]
- "She Moved Through the Fair" – A traditional Irish folk song.[11]
- "As I Was Walking One Morning in May" is in an Irish air in C Mixolydian[12][13]

46.5.2 Popular

- "Let It Loose"[14] by The Rolling Stones
- "Marquee Moon" by Television[15][16]
- Theme From *Star Trek*[17]
- "Sweet Home Alabama" by Lynyrd Skynyrd[10]

- "Sweet Child o' Mine" (solo is in E♭ natural minor) by Guns N' Roses[18]
- "Norwegian Wood" by The Beatles (with some verses in Dorian mode)[10][19][20]
- The Allman Brothers Band's "Ramblin' Man" (with blues flavoring)[20]
- "Gloria" by Them[21]
- "The Wreck of the Edmund Fitzgerald" by Gordon Lightfoot[22]
- "Express Yourself" by Madonna[21]
- "You and I" by Lady Gaga[23]
- "Hey Jude" by the Beatles ("outro" section only)[24]
- "Dark Star" by the Grateful Dead, modal in A Mixolydian[25]
- "Morning Mr Magpie" by Radiohead[26]
- "Royals" by Lorde[27]

46.6 See also

Chapter 47

Ionian mode

Ionian mode on C Play .

Ionian mode is the name assigned by Heinrich Glarean in 1547 to his new authentic mode on C (mode 11 in his numbering scheme), which uses the diatonic octave species from C to the C an octave higher, divided at G (as its dominant, reciting note or *tenor*) into a fourth species of perfect fifth (tone–tone–semitone–tone) plus a third species of perfect fourth (tone–tone–semitone): C D E F G + G A B C (Powers 2001a). This octave species is essentially the same as the major mode of tonal music (Jones 1974, 42).

Church music was previously explained by theorists as being organised in eight musical modes: the scales on D, E, F, and G in the "greater perfect system" of "musica recta" (Powers 2001b, §II: "Medieval Modal Theory"), each with their authentic and plagal counterparts.

Glarean's twelfth mode was the plagal version of the Ionian mode, called Hypoionian (under Ionian), based on the same relative scale, but with the major third as its *tenor*, and having a melodic range from a perfect fourth below the tonic, to a perfect fifth above it (Powers 2001c).

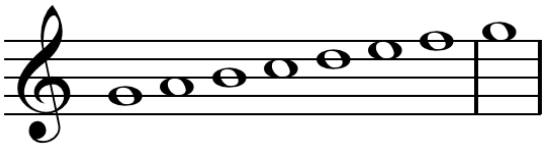
Chapter 48

Hypoionian mode



Hypoionian mode with final on C Play .

The **Hypoionian mode**, literally meaning "below Ionian", is the name assigned by Henricus Glareanus in his *Dodecachordon* (1547) to the plagal mode on C, which uses the diatonic octave species from G to the G an octave higher, divided at its final, C. This is roughly the same as playing all the white notes of a piano from G to G: G A B C ǀ (C) D E F G (Powers 2001, 37).

Glarean regarded compositions with F as the final and a one-flat signature as transpositions of the Ionian or Hypoionian mode (depending on the ambitus). Most of his contemporaries, however, appear to have continued considering such compositions as being in the fifth and sixth modes (Lydian and Hypolydian), which had been regarded since the beginnings of medieval modal theory as preferring B♭ over B♮ for the fourth degree above the final, F (Powers 2001, 37–38).

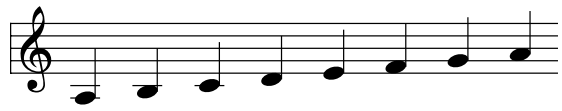
Chapter 49

Aeolian mode



Modern Aeolian mode on A. Play

The **Aeolian mode** is a musical mode or, in modern usage, a diatonic scale called the natural minor scale.

49.1 History

The word "Aeolian" in the music theory of ancient Greece was an alternative name (used by some later writers, such as Cleonides) for what Aristoxenus called the Low Lydian *tonos* (in the sense of a particular overall pitching of the musical system—not a scale), nine semitones higher than the lowest "position of the voice", which was called Hypodorian.[1] In the mid-16th century, this name was given by Heinrich Glarean to his newly defined ninth mode, with the diatonic octave species of the natural notes extending one octave from A to A—corresponding to the modern natural minor scale.[2] Up until this time, chant theory recognized eight musical modes: the relative natural scales in D, E, F and G, each with their authentic and plagal counterparts, and with the option of B-flat instead of B-natural in several modes.[3]

In 1547 Heinrich Glarean published his *Dodecachordon*. His premise had as its central idea the existence of twelve diatonic modes rather than eight, including a separate pair of modes each on the finals A and C. Finals on these notes, as well as on B♮, had been recognized in chant theory at least since Hucbald in the early tenth century, but they were regarded as merely transpositions from the regular finals a fifth lower. In the eleventh century Guido d'Arezzo, in chapter 8 of his *Micrologus*, designated these transposed finals A, B♮ and C as "affinals", and later still the term "confinal" was used in the same way.[4] In 1525, Pietro Aaron was the first theorist to explain polyphonic modal usage in terms of the eightfold system, including these transpositions.[5] As late as 1581, Illuminato Aiguino da Brescia published the most elaborate theory defending the eightfold system for polyphonic music against Glarean's innovations, in which he regarded the traditional plainchant modes 1 and 2 (Dorian and Hypodorian) at the affinal position (that is, with their finals on A instead of D) as a composite of species from two modes, which he described as "mixed modes."[6] Glarean added *Aeolian* as the name of the *new* ninth mode: the relative natural mode in A with the perfect fifth as its dominant, reciting note or *tenor*. The tenth mode, the plagal version of the Aeolian mode, Glarean called *Hypoaeolian* ("under Aeolian"), based on the same relative scale, but with the minor third as its tenor, and having a melodic range from a perfect fourth below the tonic to a perfect fifth above it.

Although scholars for the past three centuries have regarded the modes added by Glarean as the basis of the minor/major division of classical European music, as homophonic music replaced Renaissance polyphony, this is an oversimplification. Even the key of A minor is as closely related to the old transposed modes 1 and 2 (Dorian and Hypodorian) with finals on A—as well as to mode 3 (Phrygian)—as it is to Glarean's Aeolian.[7]

Aeolian on C Play .

In modern usage, the Aeolian mode is the sixth mode of the major scale and has the formula 1, 2, ♭3, 4, 5, ♭6, ♭7. In C, this is C, D, E♭, F, G, A♭, B♭ (three flats); in A, this is A, B, C, D, E, F, G (no flats or sharps).

From the point of view of its relative major key, the aeolian tonic chord is the submediant minor triad (vi). For example, if the Aeolian mode is used in its all-white-note pitch based on A, this would be an A-minor triad, which would be the submediant in the relative major key of C major.

49.2 Songs that use Aeolian mode

Aeolian mode as a scale is identical with the natural minor scale. Thus, it is ubiquitous in minor-key music. The following is a list of some examples that are distinguishable from ordinary minor tonality.

- Bob Dylan - "All Along the Watchtower"[8]
- R.E.M. - "Losing My Religion"[8]

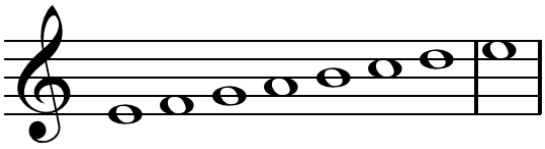
Chapter 50

Hypoaeolian mode



Hypoaeolian mode on A Play .

The **Hypoaeolian mode**, literally meaning "below Aeolian", is the name assigned by Henricus Glareanus in his *Dodecachordon* (1547) to the musical plagal mode on A, which uses the diatonic octave species from E to the E an octave above, divided by the final into a second-species fourth (semitone–tone–tone) plus a first-species fifth (tone–semitone–tone–tone): E F G A + A B C D E (Powers 2001). The tenor or reciting tone is C, mediant B, the participants are the low and high Es, the conceded modulations are G and D, and the absolute initials are E, G, A, B, and C (Rockstro 1880, 342).

For his plainchant examples Glarean proposed two important and well-known Gregorian melodies normally written with their finals on A: the antiphon *Benedicta tu in mulieribus* (traditionally designated as transposed Hypophrygian) and the gradual *Haec dies—Justus ut palma* (traditionally designated as transposed Hypodorian) (Powers 2001).

A polyphonic example of the Hypoaeolian mode is motet 19 from Palestrina's *Liber quartus* of five-voice motets on the Song of Solomon (Dickson 1937, 152).

Chapter 51

Locrian mode

Locrian on C Play .

The **Locrian mode** is either a musical mode or simply a diatonic scale.

51.1 History

Although the term occurs in several classical authors on music theory, including Cleonides (as an octave species) and Athenaeus (as an obsolete *harmonia*), there is no warrant for the modern usage of Locrian as equivalent to Glarean's Hyperaeolian mode, in either classical, Renaissance, or later phases of modal theory through the 18th century, or modern scholarship on ancient Greek musical theory and practice.[1] The name first came to be applied to modal chant theory after the 18th century,[2] when it was used to describe the mode newly numbered as mode 11, with final on B, ambitus from that note to the octave above, and with semitones therefore between the first and second, and fourth and fifth degrees. Its reciting tone (or tenor) is G, its mediant D, and it has two participants: E and F.[3] The final, as its name implies, is the tone on which the chant eventually settles, and corresponds to the tonic in tonal music. The reciting tone is the tone around which the melody principally centres,[4] the mediant is named from its position between the final and reciting tone, and the participant is an auxiliary note, generally adjacent to the mediant in authentic modes and, in the plagal forms, coincident with the reciting tone of the corresponding authentic mode.[5]

51.2 Modern Locrian

In modern practice, the Locrian may be considered to be a minor scale with the second and fifth scale degrees lowered a semitone. The Locrian mode may also be considered to be a scale beginning on the seventh scale degree of any Ionian, or major scale. The Locrian mode has the formula 1, ♭2, ♭3, 4, ♭5, ♭6, ♭7. Its tonic chord is a diminished triad (Bdim in the Locrian mode of the diatonic scale corresponding to C major).

Some examples:

- The B Locrian mode starts on B and contains the same notes as the C Major scale. (B, C, D, E, F, G, A, B)
- The E Locrian mode starts on E and contains the same notes as the F Major scale. (E, F, G, A, B♭, C, D, E)
- The G Locrian mode starts on G and contains the same notes as the A♭ Major scale. (G, A♭, B♭, C, D♭, E♭, F, G)
- The F♯ Locrian mode starts on F♯ and contains the same notes as the G Major scale. (F♯, G, A, B, C, D, E, F♯)

Locrian on B.

51.3 Overview

The Locrian mode is the only modern diatonic mode in which the tonic triad is a diminished chord, which is considered dissonant. This is because the interval between the root and fifth of the chord is a diminished fifth. For example, the tonic triad of B Locrian is made from the notes B, D, F. The root is B and the fifth is F. The diminished-fifth interval between them is the cause for the chord's dissonance. Although in some practices, the fifth may be omitted from the tonic chord.

The name "Locrian" is taken from music theory of ancient Greece. However, what is now called the Locrian mode was what the Greeks called the Diatonic Mixolydian tonos. The Greeks used the term "Locrian" as an alternative name for their "Hypodorian", or "Common" tonos, with a scale running from *mese* to *nete hyperbolaion*, which in its diatonic genus corresponds to the modern Aeolian mode.[6] In his reform of modal theory in the *Dodecachordon* (1547), Heinrich Glarean named this division of the octave "Hyperaeolian" and printed some musical examples (a three-part polyphonic example specially commissioned from his friend Sixtus Dietrich, and the Christe from a mass by Pierre de La Rue), though he did not accept Hyperaeolian as one of his twelve modes.[7] The usage of the term "Locrian" as equivalent to Glarean's Hyperaeolian or the ancient Greek (diatonic) Mixolydian, however, has no authority before the 19th century.[8]

51.4 Usage

There are brief passages in works by Rachmaninov (Prelude in B minor, op. 32, no. 10), Hindemith (Ludus Tonalis), and Sibelius (Symphony no. 4 in A minor, op. 63) that have been, or may be, regarded as in the Locrian mode.[9]

Debussy's *Jeux* has three extended passages in the Locrian mode.[10]

The theme of the second movement ("Turandot Scherzo") of Hindemith's *Symphonic Metamorphosis of Themes by Carl Maria von Weber* (1943) alternates sections in Mixolydian and Locrian modes, ending in Locrian.[11]

English folk musician John Kirkpatrick's song "Dust to Dust" was written in the Locrian mode, backed by his accordion.[12] The Locrian mode is not at all traditional in English music, but was used by Kirkpatrick as a musical innovation.

Icelandic singer-songwriter Björk used the Locrian mode for the bass part of her 1995 hit "Army of Me".[13]

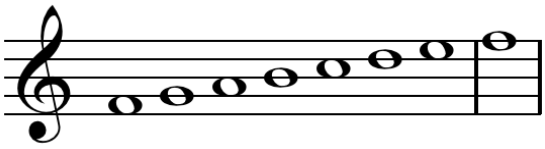
Chapter 52

Hypolocrian mode



Hypolocrian mode on B Play

The **Hypolocrian mode** is an almost entirely theoretical mode, introduced into chant theory in the 19th century by the editors of the Pustet-Ratisbon, Mechlin, and Rheims-Cambrai Office-Books, who designated it mode 12. It is the plagal counterpart to the authentic Locrian mode, mode 11 in that system of numbering, in which the Ionian and Hypoionian become modes 13 and 14 (Rockstro 1880b, 342). The ambitus of the mode lies between F and the F an octave higher, divided at the final, B. Its reciting tone (or tenor), is E, and its mediant is D. It has two participants, G and C. Although a few plainchant melodies, as well as polyphonic compositions, have been attributed to this mode by some writers, it will generally be found that they are really derived, by transposition, from some other tonality (Rockstro 1880a).

Chapter 53

Byzantine music

Byzantine music (Modern Greek: Βυζαντινή μουσική) is the music of the Medieval Roman Empire. The ecclesiastical forms of Byzantine music, composed to Greek texts as ceremonial, festival, or church music,[1] are, today, the most well-known forms. Greek and foreign historians agree that the ecclesiastical tones and in general the whole system of Byzantine music is closely related to the ancient Greek system.[2] It remains the oldest genre of extant music, of which the manner of performance and (with increasing accuracy from the 5th century onwards) the names of the composers, and sometimes the particulars of each musical work's circumstances, are known.

53.1 Early years

The term Byzantine music is commonly associated with the medieval sacred chant of Christian Churches following the Constantinopolitan Rite. The identification of "Byzantine music" with "Eastern Christian liturgical chant" is a misconception due to historical cultural reasons. Its main cause is the leading role of the Church as bearer of learning and official culture in the Eastern Roman Empire (Byzantium), a phenomenon that was not always that extreme but that was exacerbated towards the end of the empire's reign (14th century onwards) as great secular scholars migrated away from a declining Constantinople to rising western cities, bringing with them much of the learning that would spur the development of the European Renaissance. The shrinking of Greek speaking official culture around a church nucleus was even more accentuated by political force when the official culture of the court changed after the capture of Constantinople by the Ottoman Empire on May 29, 1453.

53.1.1 The Pythagorean and the Neo-Pythagorean concept of cyclical mathematics

Despite censorship and the decline of knowledge which marks the rise of Christian civilization within Hellenism, certain concepts of knowledge and education did still survive during the imperial age, when Christianity became the official religion. The Pythagorean sect and music as part of the four "cyclical exercises" (οἱ ἐγκυκλικοί μαθήματα) which preceded the Latin quadrivium and science today based on mathematics, established mainly among Greeks in southern Italy (at Tarent and Croton). Greek anachoretes of the early Middle Ages did still follow this education. The Calabrian Cassiodorus founded Vivarium where he translated Greek, and John of Damascus who learnt Greek from a Calabrian monk Kosmas, a slave in the household of his privileged father at Damascus, mentioned mathematics as part of the speculative philosophy.[3] The mathematic science of harmonics was never mixed with the concrete topics of a chant manual.

Nevertheless, Byzantine music is modal and entirely dependent on the Ancient Greek concept of harmonics. Its tonal system is based on a synthesis with ancient Greek models,[4] but we have no sources left which explain us, how this synthesis was done. Carolingian cantors could mix the science of harmonics with a discussion of church tones, named after the ethnic names of the octave species and their transposition tropes, because they invented an own octoechos on the basis of the Byzantine one. But they made no use of earlier Pythagorean concepts which had been fundamental for Byzantine music like:

It is not evident by the sources, when exactly the position of the minor or half tone moved between the devteros and tritos. It seems that the fixed degrees (hestotes) became part of a new concept of the echos as melodic mode (not simply octave species), after the echoi had been called by the ethnic names of the tropes.

The tradition of eastern liturgical chant, encompassing the Greek-speaking world, developed in the Byzantine Empire from the establishment of its capital, Constantinople, in 330 until its fall in 1453. It is undeniably of composite origin, drawing on the artistic and technical productions of the classical Greek age and inspired by the monophonic vocal music that evolved in the early Greek Christian cities of Alexandria, Antioch and Ephesus.[5] It was imitated by musicians of the 7th century to create Arab music as a synthesis of Byzantine and Persian music, and these exchanges were continued through the Ottoman Empire until Istanbul today.

53.1.2 Instruments between the Byzantine and the Carolingian court

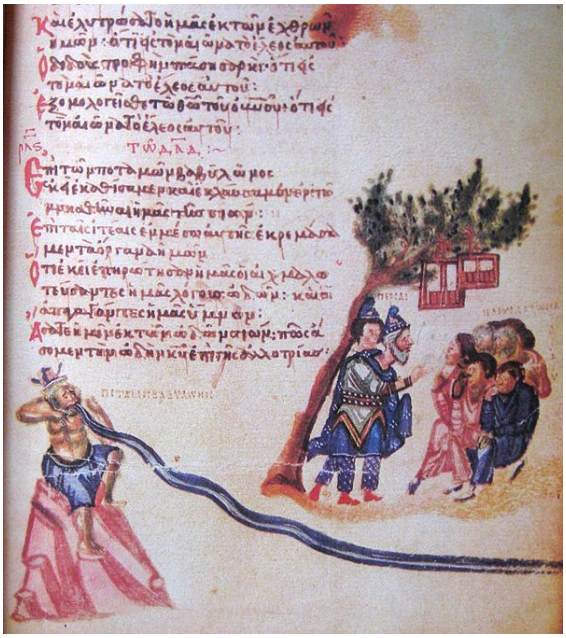
Earliest known depiction of lyra in a Byzantine ivory casket

The 9th century Persian geographer Ibn Khurradadhbih (d. 911); in his lexicographical discussion of instruments cited the lyra (lūrā) as the typical instrument of the Byzantines along with the *urghun* (organ), *shilyani* (probably a type of harp or lyre) and the *salandj* (a bagpipe).[6] The first of these, the bowed stringed instrument known as the Byzantine lyra, would come to be called the *lira da braccio*,[7] in Venice, where is it considered by many to have been the predecessor of the contemporary violin, which first flourished there.[8] The bowed "lyra" is still played in former Byzantine regions, where it is known as the Politiki lyra (lit. "lyra of the City" i.e. Constantinople) in Greece, the Calabrian lira in Southern Italy, and the Lijerica in Dalmatia. The second Byzantine instrument mentioned by Ibn Khurradadhbih, the organ, originated in the East (see Hydraulis) and was used in the Hippodrome. A pipe organ with "great leaden pipes" was sent by the emperor Constantine V to Pepin the Short King of the Franks in 757. Pepin's son Charlemagne requested a similar organ for his chapel in Aachen in 812, beginning its establishment in Western church music.[9] The final Byzantine instrument, the bagpipes, known as *Dankiyo* (from ancient Greek: angion (Τὸ ἀγγεῖον) "the container"), had been played even in Roman times. Dio Chrysostom wrote in the 1st century of a contemporary sovereign (possibly Nero) who could play a pipe (tibia, Roman reedpipes similar to Greek aulos) with his mouth as well as with a bladder under his armpit.[10] They continued to be played throughout the empire's former realms through to the present. (See Balkan Gaida, Serbo-Croatian Diple, Greek Tsampouna, Pontic Tulum, Cretan Askomandoura, Armenian Parkapzuk, Georgian Gudastviri, and Romanian Cimpoi.)

53.1.3 Acclamations at the court and the Book of Ceremonies

Another genre which lies between liturgical chant and court ceremonial are the so-called polychronia and acclamations. The acclamations by the choir to announce the entrance of the Emperor in the court or in the cathedral can be distinct from polychronia, prayers of the deacon for present political rulers which are usually answered by a choir with formulas like "Lord have mercy on us/them" (κύριε ἐλέησον).[11] The documented polychronia in books of the cathedral rite allow a geographical and a chronological classification of the manuscript and they are still used during ektenies of the divine liturgies of national Orthodox ceremonies today.

53.1.4 The Desert Fathers and urban monasticism



Chludov Psalter, 9th century (Moscow, Hist. Museum Ms. D.129, fol. 135) River of Babylon as illustration of Ps. 137:1-3

Two concepts must be understood to appreciate fully the function of music in Byzantine worship and they were related to a new form of urban monasticism which even formed the representative cathedral rites of the imperial ages which had to baptise many catechumens.

The first, which retained currency in Greek theological and mystical speculation until the dissolution of the empire, was the belief in the angelic transmission of sacred chant: the assumption that the early Church united men in the prayer of the angelic choirs. It was partly based on the Hebrew fundament of Christian worship, but in the particular reception of St. Basil of Caesarea's divine liturgy. John Chrysostom, since 397 Archbishop of Constantinople, abridged the long formular of Basil's divine

liturgy for the local cathedral rite.

The notion of angelic chant is certainly older than the Apocalypse account (Revelation 4:8-11), for the musical function of angels as conceived in the Old Testament is brought out clearly by Isaiah (6:1-4) and Ezekiel (3:12). Most significant in the fact, outlined in Exodus 25, that the pattern for the earthly worship of Israel was derived from heaven. The allusion is perpetuated in the writings of the early Fathers, such as Clement of Rome, Justin Martyr, Ignatius of Antioch, Athenagoras of Athens, John Chrysostom and Pseudo-Dionysius the Areopagite. It receives acknowledgement later in the liturgical treatises of Nicolas Kavasilas and Symeon of Thessaloniki.[12]

The second, less permanent, concept was that of koinonia or "communion". This was less permanent because, after the fourth century, when it was analyzed and integrated into a theological system, the bond and “oneness” that united the clergy and the faithful in liturgical worship was less potent. It is, however, one of the key ideas for understanding a number of realities for which we now have different names. With regard to musical performance, this concept of koinonia may be applied to the primitive use of the word choros. It referred, not to a separate group within the congregation entrusted with musical responsibilities, but to the congregation as a whole. St. Ignatius wrote to the Church in Ephesus in the following way:

> You must every man of you join in a choir so that being harmonious and in concord and taking the keynote of God in unison, you may sing with one voice through Jesus Christ to the Father, so that He may hear you and through your good deeds recognize that you are parts of His Son.

A marked feature of liturgical ceremony was the active part taken by the people in its performance, particularly in the recitation or chanting of hymns, responses and psalms. The terms choros, koinonia and ekklesia were used synonymously in the early Byzantine Church. In Psalms 149 and 150, the Septuagint translated the Hebrew word *machol* (dance) by the Greek word *choros* Greek: Χορος . As a result, the early Church borrowed this word from classical antiquity as a designation for the congregation, at worship and in song in heaven and on earth both.

Concerning the practice of psalm recitation, the recitation by a congregation of educated chanters is already testified by the soloistic recitation of abridged psalms by the end of the 4th century. Later it was called prokeimenon. Hence, there was an early practice of simple psalmody which was used for the recitation of canticles and the psalter, and usually Byzantine psalters have the 15 canticles in an appendix, but the simple psalmody itself was not notated before the 13th century, in dialogue or *papadikai* treatises preceding the book sticheraria.[13] Later books like the *akolouthiai* and some *psaltika* also contain the elaborated psalmody, when a protopsaltes recited just one or two psalm verses. Between the recited psalms and canticles troparia were recited according to the same more or less elaborated psalmody. This context relates antiphonal chant genres like antiphona (kind of introits), trisagion and its substitutes, prokeimenon, allelouiarion, the later cherubikon and its substitutes, the koinonikon cycles as they were created during the 9th century. In most of the cases they were simply troparia and their repetitions or segments were given by the antiphonon, whether it was sung or not, its three sections of the psalmodic recitation were separated by the troparion.

The recitation of the biblical odes

Chludov Psalter, beginning of the canticles

The fashion in all cathedral rites of the Mediterranean was a new emphasis on the psalter. In older ceremonies before Christianity became the religion of empires, the recitation of the biblical odes (mainly taken from the Old Testament) was much more important. They did not disappear in certain cathedral rites, like the Milanese and the Constantinopolitan rite.

Before long, however, a clericalizing tendency soon began to manifest itself in linguistic usage, particularly after the Council of Laodicea, whose fifteenth Canon permitted only the canonical *psaltai*, “chanters,” to sing at the services. The word choros came to refer to the special priestly function in the liturgy - just as, architecturally speaking, the choir became a reserved area near the sanctuary - and choros eventually became the equivalent of the word kleros (the pulpits of two or even five choirs).

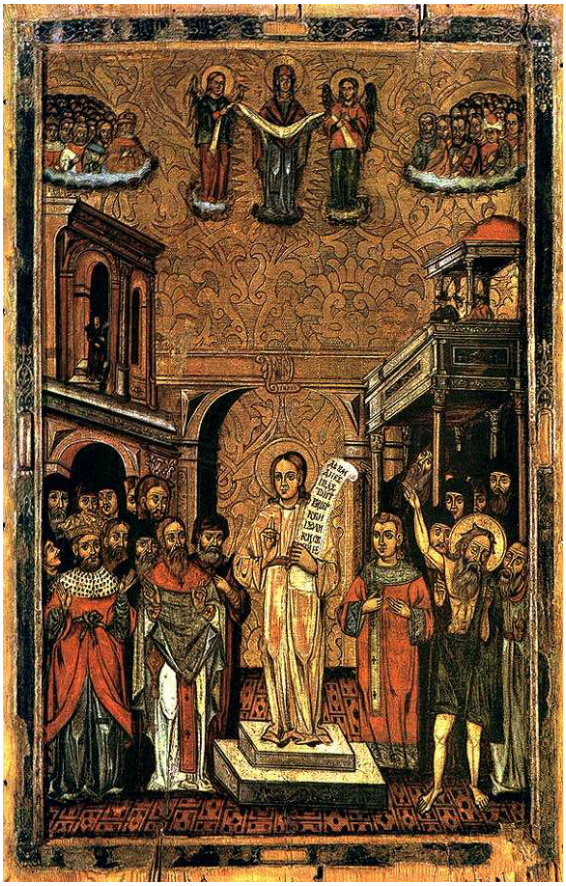
The nine canticles or odes were:

- (1) The Song of the sea (Exodus 15:1-19);
- (2) The Song of Moses (Deuteronomy 32:1-43);
- (3) - (6) The prayers of Hannah, Habakkuk, Isaiah, Jonah (1 Kings [1 Samuel] 2:1-10; Habakkuk 3:1-19; Isaiah 26:9-20; Jonah 2:3-10);

- (7) - (8) The Prayer of Azariah and Song of the Three Holy Children (Apoc. Daniel 3:26-56 and 3:57-88);
- (9) The Magnificat and the Benedictus (Luke 1:46-55 and 68-79).

and in Constantinople they were combined in pairs against the canonical order:[14]

- Ps. 17 with troparia Ἀλληλούϊα and Μνήσθητί μου, κύριε.
- (1) with troparion Τῷ κυρίῳ ἄισωμεν, ἐνδόξως γὰρ δεδόξασται.
- (2) with troparion Δόξα σοι, ὁ θεός. (Deut. 1-14) Φύλαξόν με, κύριε. (Deut. 15-21) Δίκαιος εἶ, κύριε, (Deut. 22-38) Δόξα σοι, δόξα σοι. (Deut. 39-43) Εἰσάκουσόν μου, κύριε. (3)
- (4) & (6) with troparion Οἰκτείρησόν με, κύριε.
- (3) & (9a) with troparion Ἐλέησόν με, κύριε.
- (5) & Mannaseh (apokr. 2 Chr 33) with troparion Ἰλάσθητί μοι, κύριε.
- (7) which has a refrain in itself.



An icon depicting Romanos the Melodist, c. 490–556

The troparion

The common term for a short hymn of one stanza, or one of a series of stanzas, is troparion. As a refrain interpolated between psalm verses it had the same function like the antiphon in Western plainchant. The simplest troparion was probably "allelouia", and similar to troparia like the trisagion or the cherubikon or the koinonika a lot of troparia became a chant genre of their own.

A famous example, whose existence is attested as early as the 4th century, is the Easter Vespers hymn, *Phos Hilaron* ("O Resplendent Light"). Perhaps the earliest set of troparia of known authorship are those of the monk Auxentios (first half of the 5th century), attested in his biography but not preserved in any later Byzantine order of service. Another, *O Monogenes Yios* ("Only Begotten Son"), ascribed to the emperor Justinian I (527-565), followed the doxology of the second antiphonon at the beginning of the Divine Liturgy.

53.1.5 Romanos the Melodist, the kontakion, and the Justinian Hagia Sophia

The development of large scale hymnographic forms begins in the fifth century with the rise of the kontakion, a long and elaborate metrical sermon, reputedly of Syriac origin, which finds its acme in the work of St. Romanos the Melodist (6th century). This dramatic homily, which usually paraphrases a Biblical narrative, comprises some 20 to 30 stanzas and was sung during the Morning Office (Orthros) in a simple and direct syllabic style (one note per syllable). The earliest musical versions, however, are melismatic (that is, many notes per syllable of text), and belong to the time of the ninth century and later when *kontakia* were reduced to the *prooimion* (introductory verse) and first *oikos* (stanza, literally "house"). Romanos' own recitation of all the numerous *oikoi* must have been much simpler, but the most interesting question of the genre are the different functions that *kontakia* once had.

Some of them had a clear liturgical assignation, others not. Some of Romanos creations can be even regarded as political propaganda in connection with the new and very fast reconstruction of the famous Hagia Sophia by Isidore of Miletus and Anthemius of Tralles, after a hole quarter of Constantinople had been burnt down during a civil war, after Justinian had ordered its violent desctruction and a massacre at the hippodrome.[15]

Icon screen of SS. Forty Martyrs Church at Veliko Tarnovo (Bulgaria)

53.1.6 Changes in architecture and liturgy, and the introduction of the cherubikon

Main article: Cherubikon

The separation of the prothesis where the bread was consecrated during a separated service called proskomide, required a procession of the gifts at the beginning of the second eucharist part of the divine liturgy. The troparion "Οἱ τὰ χερουβὶμ" was often ascribed to Emperor Justin II, but the changes in sacral architecture were definitely traced back to his time by archaeologues.[16] It seems that the cherubikon was a prototype of the Western chant genre offertory.

With this change came also a choir screen before the bema (sanctuary) and the dramaturgy of three doors which were closed and opened during the ceremony. Outside Constantinople these choir or icon screens of marble were later replaced by iconostaseis.

53.1.7 Monastic reforms at Constantinople and Palestine

By the end of the seventh century, the kontakion, Romanos' genre which more or less replaced the former canticle recitation, was overshadowed by a new monastic type of homiletic hymn, the *kanon*. Essentially, the kanon is an hymnodic complex composed of nine odes which were originally attached to the nine Biblical canticles and to which they were related by means of corresponding poetic allusion or textual quotation (see the section about the biblical odes). Out of the custom of canticle recitation, monastic reformers at Constantinople, Jerusalem and Mount Sinai developed a new homiletic genre whose verses in the complex ode meter were composed over a melodic model: the heirmos.[17]

The nine heirmoi, however, are metrically dissimilar; consequently, an entire kanon comprises nine independent melodies (eight, when the second ode is omitted), which are united musically by the same mode and textually by references to the general theme of the liturgical occasion, and sometimes by an acrostic.

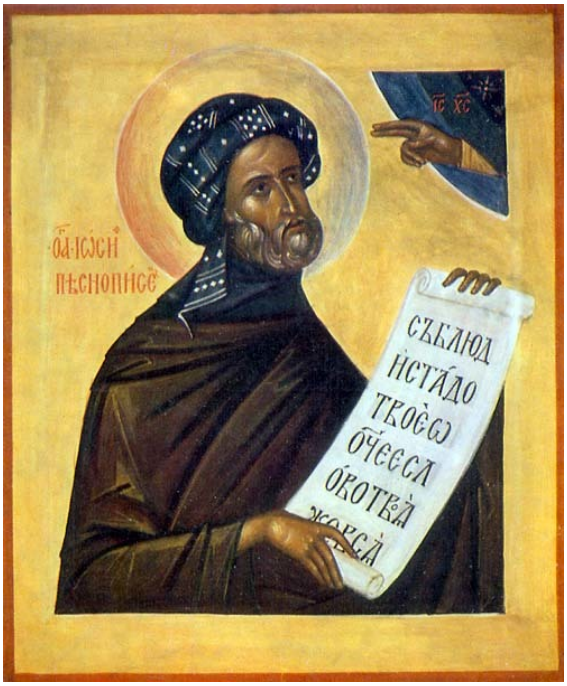
The earliest examples were composed during the 6th century and have mainly survived in the Georgian Iadgari tropologion.[18] After the octoechos reform of the Quinisext Council in 692, especially monks at Mar Saba like St. Andrew of Crete (ca. 660-ca. 740), Saints John of Damascus and Cosmas of Jerusalem composed in these genres.

Today the second ode is usually omitted, but it was medieval custom, that the extremely strict spirit of Moses' last prayer was recited during Lenten period.

53.2 The monastic reform of the Stoudites and their notated chant books

Saint Kassia, c. 810–865

Another kind of hymn, important both for its number and for the variety of its liturgical use and its early development which is already testified in 6th-century tropologia, is the *sticheron*. Festal stichera, accompanying both the fixed psalms at the beginning and end of Vespers and the psalmody of the Lauds (the Ainoi) in the Morning Office, exist for all special days of the year, the Sundays and weekdays of Lent, and for the recurrent cycle of eight



Joseph the Hymnographer, born c. 810

weeks in the order of the modes beginning with Easter. Their melodies were originally preserved in the *tropologion*. During the 9th century two new notated chant book were created at the Stoudios Monastery which were supposed to replace the tropologion: the *sticherarion*, consisting of the idiomela in the *menaion* (fixed cycle), the *triodion* and the *pentekostarion* (mobile cycle around the holy week), and the *octoechos* (hymns of the weekly cycle), a bulky volume which first appeared in the middle of the tenth century and contains over a thousand model troparia, and the *heirmologion* which was either composed according to the eight echoi or according to the nine odes of the canon. These books were not only provided with musical notation, with respect to the former *tropologia* they were also considerably more elaborated and varied as a collection of various local traditions. In practice it meant that only a small part of the repertory was really chosen to be sung during the divine services.

The new custom established by the reformer was that each ode consists of an initial troparion, the heirmos, followed by three, four or more troparia from the menaion which are the exact metrical reproductions of the heirmos (akrostics), thereby allowing the same music to fit all troparia equally well.

53.2.1 The cyclic organization of lectionaries

Byzantine chant manuscripts date from the 9th century, while lectionaries of biblical readings in Ekphonetic notation (a primitive graphic system designed to indicate the manner of reciting lessons from Scripture) begin about a century earlier and continue in use until the 12th or 13th century. Our knowledge of the older period is derived from Church service books *Typika*, patristic writings and medieval histories. Scattered examples of hymn texts from the early centuries of Greek Christianity still exist. Some of these employ the metrical schemes of classical Greek poetry; but the change of pronunciation had rendered those meters largely meaningless, and, except when classical forms were imitated, Byzantine hymns of the following centuries are prose-poetry, unrhymed verses of irregular length and accentual patterns.

The effect that this concept had on church music was threefold: first, it bred a highly conservative attitude to musical composition; secondly, it stabilized the melodic tradition of certain hymns; and thirdly, it continued, for a time, the anonymity of the composer. For if a chant is of heavenly origin, then the acknowledgment received by man in transmitting it to posterity ought to be minimal. This is especially true when he deals with hymns which were known to have been first sung by angelic choirs - such as the Amen, Alleluia, Trisagion, Sanctus and Doxology. Consequently, until Palaeologan times, it was inconceivable for a composer to place his name beside a notated text in the manuscripts.

53.2.2 The Hagiopolites treatise

Main article: Hagiopolitan Octoechos

The earliest chant manual pretends right at the beginning that John of Damascus was its author. Its first edition was based on a more or less complete version in a 14th-century manuscript,[19] but it is widely accepted that it was part of the reform redaction of the tropologia by the end of the 8th century, after Irene's Council of Nikaia had confirmed the octoechos reform of 692 in 787. It fits well to the later focus on Palestine authors in the new chant book heirmologion.

Concerning the octoechos, the Hagiopolitan system is characterised as a system of eight diatonic echoi with two additional phthorai, which were not used by John of Damascus, but by Joseph the Hymnographer. It also mentions an alternative system of the Asma (the cathedral rite was called ἀκολουθία ᾄσματική) which consisted of 4 kyrioi echoi, 4 plagioi, 4 mesoi, and 4 phthorai. It seems that until the time, when the Hagiopolites was written, the octoechos reform did not work out for the cathedral rite, because singers at the court and at the Patrairchate still used a tonal system of 16 echoi which was obviously part of the particular notation of their books: the asmatikon and the kontakarion or psaltikon.

But neither 9th-century Constantinopolitan chant book nor an introducing treatise which explains the forementioned system of the Asma, have survived. Only a 14th-century manuscript of Kastoria testifies cheironomic signs used in the Kontakarion which are tran-

scribed in longer melodic phrases by the notation of the contemporary sticherarion, the middle Byzantine Round notation.

53.3 The Slavic reception

53.3.1 The missions of Cyril and Methodius

53.3.2 The Kievan Rus' and the earliest manuscripts of the cathedral rite

53.4 The end of the cathedral rite at Constantinople

Ideas of originality and free invention similar to those seen in later music probably never existed in early Byzantine times. The very notion of using traditional formulas (or melody-types) as a compositional technique shows an archaic concept in liturgical chant, and is quite the opposite of free, original creation. It seems evident that the chants of the Byzantine repertory found in musical manuscripts from the tenth century to the time of the Fourth Crusade (1204–1261), represent the final and only surviving stage of an evolution, the beginnings of which go back at least to the sixth century. What exact changes took place in the music during the formative stage is difficult to say; but certain chants in use even today exhibit characteristics which may throw light on the subject. These include recitation formulas, melody-types, and standard phrases that are clearly evident in the folk music and other traditional music of various cultures of the East.

53.4.1 The kontakarion of the Norman Archimandritates

53.4.2 The kontakarion of the Peninsula Athos

53.5 The era of psaltic art and the new mixed rite of Constantinople

With the end of creative poetical composition, Byzantine chant entered its final period, devoted largely to the production of more elaborate musical settings of the traditional texts: either embellishments of the earlier simpler melodies, or original music in highly ornamental style. This was the work of the so-called *Maïstores*, "masters," of whom the most celebrated was St. John Koukouzeles (active c. 1300), compared in Byzantine writings to

A musical manuscript of 1433 from Pantokratoros monastery

St. John of Damascus himself, as an innovator in the development of chant. The multiplication of new settings and elaborations of the old continued in the centuries following the fall of Constantinople, until by the end of the eighteenth century the original musical repertory of the medieval musical manuscripts had been quite replaced by later compositions, and even the basic model system had undergone profound modification.

53.5.3 The synthesis between harmonikai and papadikai

53.6 Ottoman era

53.6.1 Chant between Raidestinos, Chrysaphes the Younger, Germanos of New Patras and Balasios

53.6.2 Petros Bereketes and the school of the Phanariotes

To a certain degree we may look for remnants of Byzantine or early (Greek-speaking, Orthodox Christian) near eastern music in the music of the Ottoman Court. Ex-

amples such as that of the eminent composer and theorist Prince Cantemir of Romania learning music from the Greek musician *Angelos*, indicate the continuing participation of Greek speaking people in court culture. The influences of ancient Greek basin and the Greek Christian chants in the Byzantine music as origin, are confirmed. Music of Turkey was influenced by Byzantine music, too (mainly in the years 1640-1712).[20] It seems also remarkable that Ottoman music is a synthesis, carrying the culture of Greek and Armenian Christian chant. It emerged as the result of a sharing process between the many civilizations which met together in the Orient, considering the breadth and length of duration of these empires and the great number of ethnicities and major or minor cultures that they encompassed or came in touch with at each stage of their development.

53.6.3 The Putna school of the Bukovina

53.6.4 Phanariotes at the new music school of the patriarchate

53.7 The Orthodox reformulation according to the new method

Chrysanthos of Madytos (ca. 1770-1846), Gregory the Protopsaltes (ca. 1778 - ca. 1821), and Chourmouzios the Archivist were responsible for a reform of the notation of Greek ecclesiastical music. Essentially, this work consisted of a simplification of the Byzantine musical symbols which, by the early 19th century, had become so complex and technical that only highly skilled chanters were able to interpret them correctly. The work of the three reformers is a landmark in the history of Greek Church music, since it introduced the system of neo-Byzantine music upon which are based the present-day chants of the Greek Orthodox Church. Unfortunately, their work has since been misinterpreted often, and much of the oral tradition has been lost.

53.7.1 Konstantinos Byzantios' renunciation of the new method

53.7.2 The old school of the patriarchate

53.7.3 The modern school of the patriarchate

53.8 The Simon Karas school at Athens

Simon Karas[21] (1905–1999) began an effort to assemble as much material as possible in order to restore the apparently lost tradition. His work is continued by Lycourgos Angelopoulos and other *psaltai* ("cantors") of Byzantine music. Two major styles of interpretation have evolved, the Hagioritic, which is simpler and is mainly followed in monasteries, and the Patriarchal, as exemplified by the style taught at the Great Church of Constantinople, which is more elaborate and is practised in parish churches. Nowadays the Orthodox churches maintain chanting schools in which new cantors are trained. Each diocese employs a *protopsaltes* ("first cantor"), who directs the diocesan cathedral choir and supervises musical education and performance. The *protopsaltes* of the Patriarchates are given the title *Archon Protopsaltes* ("Lord First Cantor"), a title also conferred as an honorific to distinguished cantors and scholars of Byzantine music.

53.9 Modern composers

Jessica Suchy-Pilalis is an example of a modern composer who writes and arranges sacred music in the Byzantine tradition. Dr. Suchy-Pilalis serves as Protopsaltes at Holy Trinity Greek Orthodox Church in Indianapolis, Indiana.[22]

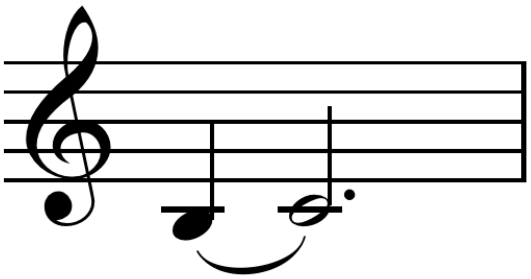
Chapter 54

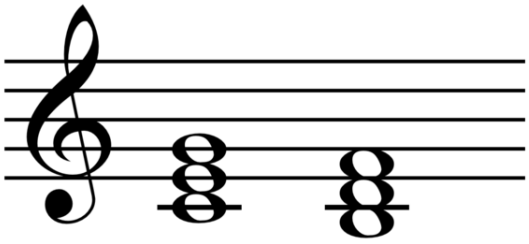
Leading-tone

For the lowered seventh degree, see subtonic.

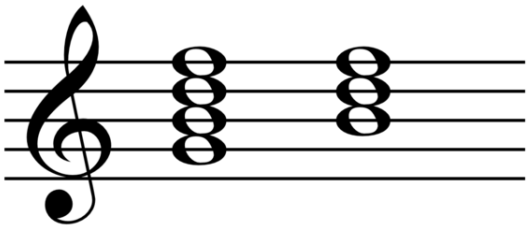
In music theory, a **leading-note** (also **subsemitone**,



Seventh scale degree, or leading-tone, leading to the first scale degree, or tonic, in C major Play EQ Play Just .

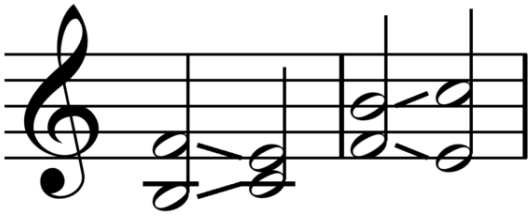


Tonic and leading tone chords in C Play . C major and B diminished (b°) chords. Play just leading tone chord

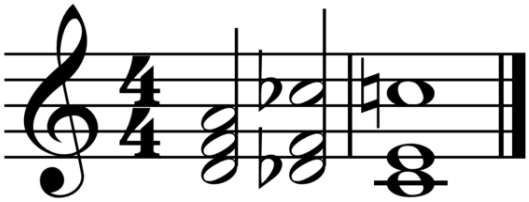


Dominant seventh and incomplete dominant seventh in C major: G7 and b° chords Play .

and called the **leading-*tone*** in the US) is a note or pitch which resolves or "leads" to a note one semitone higher or lower, being a lower and upper leading-tone, respectively.



Tritone resolution inward and outwards Play inward Play outwards . Both notes resolve by half step.



Tritone substitution, ii-subV-I on C, creates an upper leading-note (D♭, which leads down to C) play

Cadence featuring an upper leading tone from a well known 16th-century lamentation, the debate over which was documented in Rome c.1540 (Berger 1987, 148). Play upper-leading tone trill Play diatonic trill

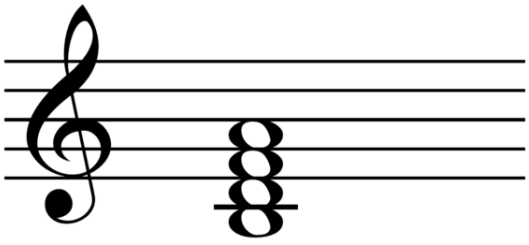
More narrowly, *the* leading tone is the seventh scale degree of the diatonic scale, with a strong affinity for and leading melodically to the tonic (Benward and Saker 2003, 203). For example, in the C major scale (white keys on a piano, starting on C), the leading note is the note B; and the leading note chord uses the notes B, D, and F: a

diminished triad. In music theory, the leading note triad is symbolized by the Roman numeral vii°. By contrast, an **upper leading-tone** (Berger 1987, 148; Coker 1991, 50), which leads *down*, may be found as the seventh of the dominant seventh chord, which leads to the third of the tonic chord (in C: F of a G7 chord lead to E of a CM chord). The upper leading-tone may also be found above the tonic, on D♭ or C♯ in C.

Seventh chord resolution from Scott Joplin's "Maple Leaf Rag" (Benward & Saker 2003, 203) Play . Note that the seventh resolves down by half step.

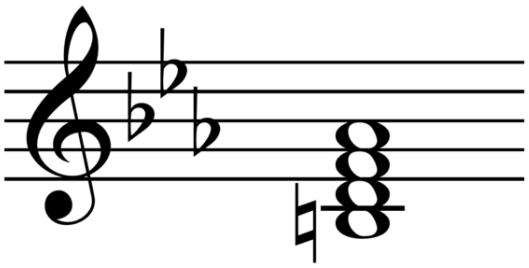
According to Ernst Kurth (1913) the major and minor thirds contain "latent" tendencies towards the perfect fourth and whole-tone, respectively, and thus establish tonality. However, Carl Dahlhaus (1990) shows that this drive is in fact created through or with harmonic function, a root progression in another voice by a whole-tone or fifth, or melodically (monophonically) by the context of the scale. For example, the leading note of alternating C chord and F minor chords is either the note E leading to F, if F is tonic, or A♭ leading to G, if C is tonic. In works from the 14th and 15th century Western tradition, the leading-note is created by the progression from imperfect to perfect dissonances, such as a major third to a perfect fifth or minor third to a unison. The same pitch outside of the imperfect consonance is not a leading note.

As a diatonic function the leading-note is the seventh scale degree of any diatonic scale when the distance between it and the tonic is a single semitone. In diatonic scales where there is a whole tone between the seventh scale degree and the tonic, such as the Mixolydian mode, the seventh degree is called instead, the subtonic.



Leading-tone seventh chord in C major: vii^{ø7} Play .

The leading-tone seventh chords are vii^{ø7} and vii^{o7} (Benward and Saker 2003, 219), in major and in minor.



Leading-tone seventh chord in C minor: vii^{o7} Play .

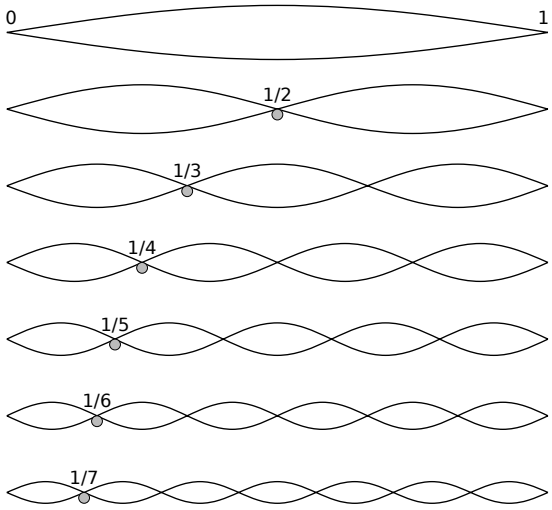
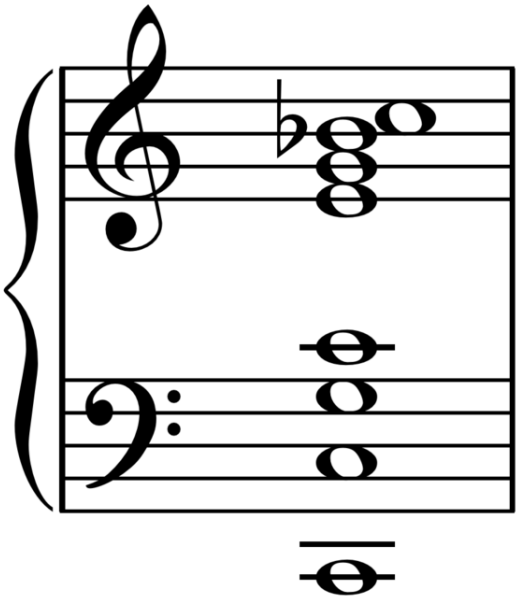
Chapter 55

Harmonic series (music)



Harmonic series of a string with terms written as reciprocals (2/1 written as 1/2)



First eight harmonics on C. Play simultaneously

A **harmonic series** is the sequence of all multiples of a base frequency.

Pitched musical instruments are often based on an approximate harmonic oscillator such as a string or a column of air, which oscillates at numerous frequencies simultaneously. At these resonant frequencies, waves travel in both directions along the string or air column, reinforcing and canceling each other to form standing waves. Interaction with the surrounding air causes audible sound waves, which travel away from the instrument. Because of the typical spacing of the resonances, these frequencies are mostly limited to integer multiples, or harmonics, of the lowest frequency, and such multiples form the harmonic series (see harmonic series (mathematics)).

The musical pitch of a note is usually perceived as the lowest partial present (the fundamental frequency), which may be the one created by vibration over the full length of the string or air column, or a higher harmonic chosen by the player. The musical timbre of a steady tone from such an instrument is determined by the relative strengths of each harmonic.

55.1 Terminology

55.1.1 Partial, harmonic, fundamental, inharmonicity, and overtone

Any complex tone "can be described as a combination of many simple periodic waves (i.e., sine waves) or *partials,* each with its own frequency of vibration, amplitude, and phase."[1] (Fourier analysis)

A ***partial*** is any of the sine waves by which a complex tone is described.

A *harmonic* (or a *harmonic partial*) is any of a set of partials that are whole number multiples of a common fundamental frequency.[2] This set includes the *fundamental*, which is a whole number multiple of itself (1 times itself).

Inharmonicity is a measure of the deviation of a partial from the closest ideal harmonic, typically measured in cents for each partial.[3]

Typical pitched instruments are designed to have partials that are close to being whole-number ratios, harmonics, with very low inharmonicity; therefore, in music theory, and in instrument tuning, it is convenient to speak of the partials in those instruments' sounds as harmonics, even if they have some inharmonicity. Other pitched instruments, especially certain percussion instruments, such as marimba, vibraphone, tubular bells, and timpani, contain mostly inharmonic partials, yet may give the ear a good sense of pitch. Unpitched, or indefinite-pitched instruments, such as cymbals, gongs, or tam-tams make sounds (produce spectra) rich in inharmonic partials.

An *overtone* is any partial except the lowest. Overtone does not imply harmonicity or inharmonicity and has no other special meaning other than to exclude the fundamental. This can lead to numbering confusion when comparing overtones to partials; the first overtone is the second partial.

Some electronic instruments, such as theremins and synthesizers, can play a pure frequency with no overtones, although synthesizers can also combine frequencies into more complex tones, for example to simulate other instruments. Certain flutes and ocarinas are very nearly without overtones.

55.2 Frequencies, wavelengths, and musical intervals in example systems

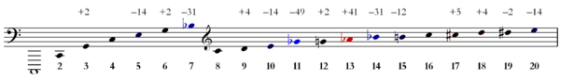
The simplest case to visualise is a vibrating string, as in the illustration; the string has fixed points at each end, and each harmonic mode divides it into 1, 2, 3, 4, etc., equal-sized sections resonating at increasingly higher frequencies.[4] Similar arguments apply to vibrating air columns in wind instruments, although these are complicated by having the possibility of anti-nodes (that is, the air column is closed at one end and open at the other), conical as opposed to cylindrical bores, or end-openings that run the gamut from no flare (bell), cone flare (bell), or exponentially shaped flares (bells).

In most pitched musical instruments, the fundamental (first harmonic) is accompanied by other, higher-frequency harmonics. Thus shorter-wavelength, higher-frequency waves occur with varying prominence and give each instrument its characteristic tone quality. The fact that a string is fixed at each end means that the longest allowed wavelength on the string (giving the fundamental frequency) is twice the length of the string (one round trip, with a half cycle fitting between the nodes at the two ends). Other allowed wavelengths are 1/2, 1/3, 1/4, 1/5, 1/6, etc. times that of the fundamental.

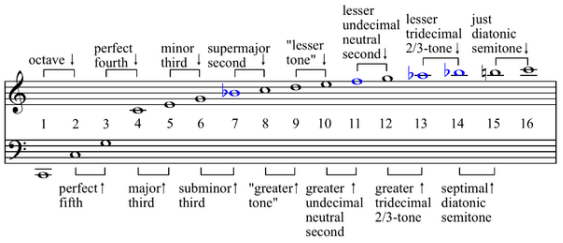
Theoretically, these shorter wavelengths correspond to vibrations at frequencies that are 2, 3, 4, 5, 6, etc., times the fundamental frequency. Physical characteristics of the vibrating medium and/or the resonator it vibrates against often alter these frequencies. (See inharmonicity and stretched tuning for alterations specific to wire-stringed instruments and certain electric pianos.) However, those alterations are small, and except for precise, highly specialized tuning, it is reasonable to think of the frequencies of the harmonic series as integer multiples of the fundamental frequency.

The harmonic series is an arithmetic series (1×f, 2×f, 3×f, 4×f, 5×f, ...). In terms of frequency (measured in cycles per second, or hertz (Hz) where f is the fundamental frequency), the difference between consecutive harmonics is therefore constant and equal to the fundamental. But because human ears respond to sound nonlinearly, higher harmonics are perceived as "closer together" than lower ones. On the other hand, the octave series is a geometric progression (2×f, 4×f, 8×f, 16×f, ...), and people hear these distances as "the same" in the sense of musical interval. In terms of what one hears, each octave in the harmonic series is divided into increasingly "smaller" and more numerous intervals.

The second harmonic, whose frequency is twice of the fundamental, sounds an octave higher; the third harmonic, three times the frequency of the fundamental, sounds a perfect fifth above the second. The fourth harmonic vibrates at four times the frequency of the fundamental and sounds a perfect fourth above the third (two octaves above the fundamental). Double the harmonic number means double the frequency (which sounds an octave higher).



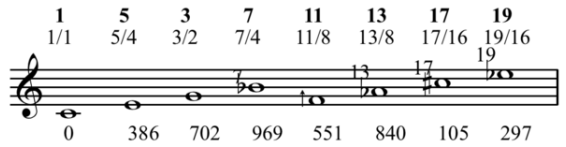
An illustration of the harmonic series in musical notation. The numbers above the harmonic indicate the number of cents difference from equal temperament (rounded to the nearest cent). Blue notes are flat and red notes are sharp.



Harmonic series as musical notation with intervals between harmonics labeled. Blue notes differ most significantly from equal temperament. You can listen to A2 (110 Hz) and 15 of its partials

55.3 Harmonics and tuning

If the harmonics are transposed into the span of one octave, they approximate some of the notes in what the



Staff notation of partials 1, 3, 5, 7, 11, 13, 17, and 19 on C.[5] *Play*

West has adopted as the chromatic scale based on the fundamental tone. The Western chromatic scale has been modified into twelve equal semitones, which is slightly out of tune with many of the harmonics, especially the 7th, 11th, and 13th harmonics. In the late 1930s, composer Paul Hindemith ranked musical intervals according to their relative dissonance based on these and similar harmonic relationships.

Below is a comparison between the first 31 harmonics and the intervals of 12-tone equal temperament (12TET), transposed into the span of one octave. Tinted fields highlight differences greater than 5 cents (1/20th of a semitone), which is the human ear's "just noticeable difference" for notes played one after the other (smaller differences are noticeable with notes played simultaneously).

The frequencies of the harmonic series, being integer multiples of the fundamental frequency, are naturally related to each other by whole-numbered ratios and small whole-numbered ratios are likely the basis of the consonance of musical intervals (see just intonation). This objective structure is augmented by psychoacoustic phenomena. For example, a perfect fifth, say 200 and 300 Hz (cycles per second), causes a listener to perceive a combination tone of 100 Hz (the difference between 300 Hz and 200 Hz); that is, an octave below the lower (actual sounding) note. This 100 Hz first-order combination tone then interacts with both notes of the interval to produce second-order combination tones of 200 (300 – 100) and 100 (200 – 100) Hz and all further nth-order combination tones are all the same, being formed from various subtraction of 100, 200, and 300. When one contrasts this with a dissonant interval such as a tritone (not tempered) with a frequency ratio of 7:5 we get, for example, 700 – 500 = 200 (1st order combination tone) and 500 – 200 = 300 (2nd order). The rest of the combination tones are octaves of 100 Hz so the 7:5 interval actually contains 4 notes: 100 Hz (and its octaves), 300 Hz, 500 Hz and 700 Hz. Note that the lowest combination tone (100 Hz) is a 17th (2 octaves and a major third) below the lower (actual sounding) note of the tritone. All the intervals succumb to similar analysis as has been demonstrated by Paul Hindemith in his book *The Craft of Musical Composition*.

55.4 Timbre of musical instruments

The relative amplitudes (strengths) of the various harmonics primarily determine the timbre of different instruments and sounds, though onset transients, formants, noises, and inharmonicities also play a role. For example, the clarinet and saxophone have similar mouthpieces and reeds, and both produce sound through resonance of air inside a chamber whose mouthpiece end is considered closed. Because the clarinet's resonator is cylindrical, the even-numbered harmonics are less present. The saxophone's resonator is conical, which allows the even-numbered harmonics to sound more strongly and thus produces a more complex tone. The inharmonic ringing of the instrument's metal resonator is even more prominent in the sounds of brass instruments.

Human ears tend to group phase-coherent, harmonically-related frequency components into a single sensation. Rather than perceiving the individual partials–harmonic and inharmonic, of a musical tone, humans perceive them together as a tone color or timbre, and the overall pitch is heard as the fundamental of the harmonic series being experienced. If a sound is heard that is made up of even just a few simultaneous sine tones, and if the intervals among those tones form part of a harmonic series, the brain tends to group this input into a sensation of the pitch of the fundamental of that series, even if the fundamental is not present.

Variations in the frequency of harmonics can also affect the *perceived* fundamental pitch. These variations, most clearly documented in the piano and other stringed instruments but also apparent in brass instruments, are caused by a combination of metal stiffness and the interaction of the vibrating air or string with the resonating body of the instrument.

55.5 Interval strength

David Cope (1997) suggests the concept of interval strength,[6] in which an interval's strength, consonance, or stability (see consonance and dissonance) is determined by its approximation to a lower and stronger, or higher and weaker, position in the harmonic series. See also: Lipps–Meyer law.

Thus, an equal-tempered perfect fifth (play) is stronger than an equal-tempered minor third (play), since they approximate a just perfect fifth (play) and just minor third (play), respectively. The just minor third appears between harmonics 5 and 6 while the just fifth appears lower, between harmonics 2 and 3.

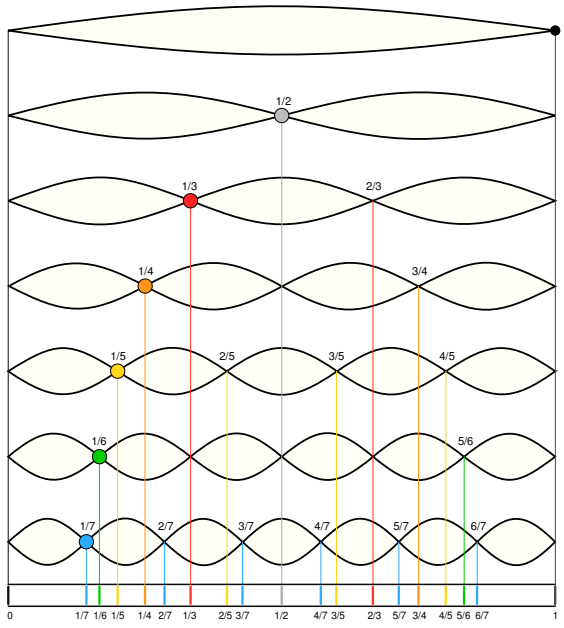
Chapter 56

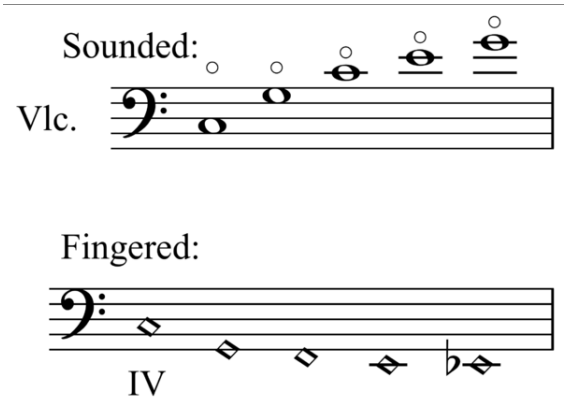
Harmonic

This article is about the components of periodic signals. For other uses, see Harmonic (disambiguation).

A **harmonic** of a wave is a component frequency of the signal that is an integer multiple of the fundamental frequency, i.e. if the fundamental frequency is f, the harmonics have frequencies $2f$, $3f$, $4f$, . . . etc. The harmonics have the property that they are all periodic at the fundamental frequency, therefore the sum of harmonics is also periodic at that frequency. Harmonic frequencies are equally spaced by the width of the fundamental frequency and can be found by repeatedly adding that frequency. For example, if the fundamental frequency (first harmonic) is 25 Hz, the frequencies of the next harmonics are: 50 Hz (2nd harmonic), 75 Hz (3rd harmonic), 100 Hz (4th harmonic) etc.



The nodes of a vibrating string are harmonics.



Two different notations of natural harmonics on the cello. First as sounded (more common), then as fingered (easier to sightread).

56.1 Characteristics

Many oscillators, including the human voice, a bowed violin string, or an Cepheid variable star, are more or less periodic, and so composed of harmonics, also known as *harmonic partials*.

Most passive oscillators, such as a plucked guitar string or a struck drum head or struck bell, naturally oscillate at not one, but several frequencies known as partials. When the oscillator is long and thin, such as a guitar string, or the column of air in a trumpet, many of the partials are integer multiples of the fundamental frequency; these are called harmonics. Sounds made by long, thin oscillators are for the most part arranged harmonically, and these sounds are generally considered to be musically pleasing. Partials whose frequencies are not integer multiples of the fundamental are referred to as *inharmonic partials*. Instruments such as cymbals, pianos, and strings plucked pizzicato create inharmonic sounds.[1][2]

The untrained human ear typically does not perceive harmonics as separate notes. Rather, a musical note composed of many harmonically related frequencies is perceived as one sound, the quality, or timbre of that sound being a result of the relative strengths of the individual harmonic frequencies. Bells have more clearly perceptible inharmonics than most instruments. Antique singing bowls are well known for their unique quality of producing multiple harmonic partials or multiphonics.

56.2 Harmonics and overtones

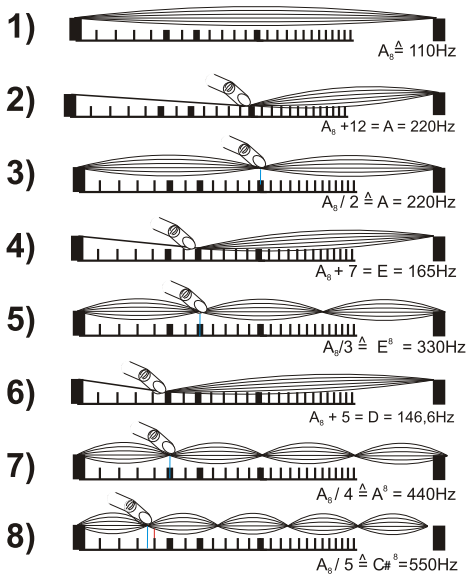
An overtone is any frequency higher than the fundamental. The tight relation between overtones and harmonics in music often leads to their being used synonymously in a strictly musical context, but they are counted differently leading to some possible confusion. This chart demonstrates how they are counted:

In many musical instruments, it is possible to play the upper harmonics without the fundamental note being present. In a simple case (e.g., recorder) this has the effect of making the note go up in pitch by an octave; but in more complex cases many other pitch variations are obtained. In some cases it also changes the timbre of the note. This is part of the normal method of obtaining higher notes in wind instruments, where it is called *overblowing*. The extended technique of playing multiphonics also produces harmonics. On string instruments it is possible to produce very pure sounding notes, called harmonics or *flageolets* by string players, which have an eerie quality, as well as being high in pitch. Harmonics may be used to check at a unison the tuning of strings that are not tuned to the unison. For example, lightly fingering the node found halfway down the highest string of a cello produces the same pitch as lightly fingering the node 1/3 of the way down the second highest string. For the human voice see Overtone singing, which uses harmonics.

While it is true that electronically produced periodic tones (e.g. square waves or other non-sinusoidal waves) have “harmonics” that are whole number multiples of the fundamental frequency, practical instruments do not all have this characteristic. For example higher “harmonics"' of piano notes are not true harmonics but are “overtones” and can be very sharp, i.e. a higher frequency than given by a pure harmonic series. This is especially true of instruments other than stringed or brass/woodwind ones, e.g., xylophone, drums, bells etc., where not all the overtones have a simple whole number ratio with the fundamental frequency.

The fundamental frequency is the reciprocal of the period of the periodic phenomenon.

This article incorporates public domain material from the General Services Administration document “Federal Standard 1037C”.



Playing a harmonic on a string

very quality that can be highly effective as a special color" when used and heard in orchestration.[3] It is unusual to encounter natural harmonics higher than the fifth partial on any stringed instrument except the double bass, on account of its much longer strings.[4]

56.3.1 Table

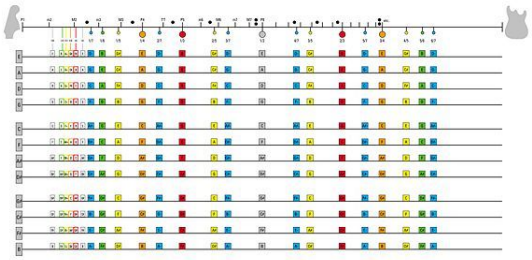


Table of harmonics of a stringed instrument with colored dots indicating which positions can be lightly fingered to generate just intervals up to the 7th harmonic

56.3 Harmonics on stringed instruments

The following table displays the stop points on a stringed instrument, such as the guitar (guitar harmonics), at which gentle touching of a string will force it into a harmonic mode when vibrated. **String harmonics** (**flageolet tones**) are described as having a “flutelike, sil-

56.3.2 Artificial harmonics

Although harmonics are most often used on open strings, occasionally a score will call for an artificial harmonic, produced by playing an overtone on a stopped string. As a performance technique, it is accomplished by using two fingers on the fingerboard, the first to shorten the string to the desired fundamental, with the second touching the node corresponding to the appropriate harmonic.

56.4 Other information

Harmonics may be either used or considered as the basis of just intonation systems. Composer Arnold Dreyblatt is able to bring out different harmonics on the single string of his modified double bass by slightly altering his unique bowing technique halfway between hitting and bowing the strings. Composer Lawrence Ball uses harmonics to generate music electronically.
